```

i've been having trouble downloading with xmodem
and was wondering if anyone could help me. i am
using xmodem on ansigraf and have been having problems
with downloads. most downloads don't work and get
into the "retry" state.

anyone know what's going on?

danny chen

Could someone repost uniterm part 6 of 6 and uEmacs v3.7i part1 ?
My site seems to have lost them, and since I don't have other
versions of uniterm or uE, I would appreciate it very much.
Thanks,

Bob Fortin

I've been using vix pretty much exclusively, and I have not had any
of the problems you mentioned. I try not to use it for very large
bodies of text, but that's mainly because my ramdisk tends to throw up
if it gets filled up to it's limit (with programs, text files,
whatever.) Also, saving the stuff every page or so is probably a good
idea. You could try getting the source and recompiling.

I called Data Pacific about the Magic Sac today. I was ready to order one when I asked about printer support. Unfortunatly, the Magic Sac emulates the Mac so well, it seems you need an Image Writer to use all the printer features of the Mac. I know enough about the Mac to know that it is really locked into the Image Writer. Does any Magic Sac owner out there have any experience using other printers?

Here is a translation of the MonST documentation from the German. Ron isn't on the net, so I'll forward comments to him.

Steve Tether

MonST.doc - Translation of manual for MonST monitor program
10/02/86 - Ron Sprunger

Corrections 10/05/86 - Ron Sprunger

*** Introduction to MonST - Version 1.0 - 3/86 ***
Program by:

Matthias Meyer
Rosenwinkel 36
2380 Schleswig
West Germany

"Looking under the keys"

MonSt is a comfortable and powerful monitor program for the Atari ST. The program is fully relocatable, and will run anywhere in memory, but not on EPROM. It makes little use of GEMDOS, and has only one XBIOS call, so it will work with all versions of TOS.

To use the program, you must have an eighty-character monitor, either high or medium resolution only.

When MonST is started, it displays the block of memory which it has occupied. The user should remember or write down these addresses in order to avoid accidentally overwriting the monitor.

Use the program with care! You are working very close to the machine itself, which means that careless memory edits can quickly crash the computer.

a) Full Screen Editor

TOS unfortunately provides only keyboard-in and picture-out routines, and not (as for instance the old Commodores) a picture-in routine. In other words, the screen cannot be read easily to pickup the changes which might have been made. For this reason, a 2000 byte buffer is used to hold the screen text, making changes directly on the screen possible. This text buffer lies just above the program code, and uses no RAM outside of the p
rogram code area (except for the exception vectors -
see "V").

- The cursor can be moved all over the screen with the cursor control keys (arrows).

- <RETURN> scans the current line, and updates memory accordingly. At the start, periods or blank positions will be skipped over. (If someone can make better sense than I can of the treatment of periods and blanks, please let me know. - RS)

- <Backspace> erases the character to the left of the cursor, and shifts the rest of the line to the left.

- <Delete> erases the character under the cursor.

- <Insert> opens an empty position.

- <Home> moves the cursor to the upper left corner of the screen.

- <Undo> moves the cursor to bottom left corner of the screen.

- <Shift-Clr> clears the screen.

- Other commands:

<Ctrl-RETURN>	Jumps to the next line WITHOUT updating memory
<Tab>	Moves cursor ten positions right
<Ctrl-I>	Inserts a line
<Ctrl-D>	Removes a line
<Ctrl-A>	Deletes to end of line
<Ctrl-C>	Abandons the edit - returns to desktop (!)
<Help>	Redisplays screen from the text buffer (see "O" command)

- The numeric keypad can be used for hex digits, "(" for "A", ")" for "B", etc. You can use "." on the keypad for Backspace.

b) Monitor Commands

The most important commands are standard, most of the others follow the convention of SMON for the C64. Lower or upper case may be used (with exceptions).

Addresses are given and received as 6-digit hex numbers.

If two addresses are used to describe the same object, the second address will be invalid.

Parameters in square brackets "[]" are optional and may be omitted.

- X
(Exit)
Leave MonST, if the "are you sure" question is answered with "y". When the program is exited in this manner, the reserved memory (about 12 KB) will not be released. The previously changed exception vectors remain pointed to MonST (see "V"). For this reason, MonST should be re-entered via a system error, such as violation of privileged memory. (Otherwise, each invocation of the program creates a new copy of MonST 12K higher in memory.) This is easily done in ST-BASIC with ?peek(-1). If no register contents have been changed, "G" returns you to BASIC. Other program errors can also be started in this manner, but you should use the disassembler to examine the position of the error, since the program counter may not be correct after a buss error ("g" points in this case to exception number 4].

- R
(Register)
Gives the contents of the processor register, which can be changed with the editor. The register contents will be given to the processor

with a GO- or Trace-Failure.

- G [05 0000]
  (Go)
  Starts a 68000 machine language program at address $050000. If no address is given, the actual value of the program counter (PC) will be used.

- M 05 0000 [05 0100]
  (Memory)
  Gives contents of RAM or ROM as a hex dump with ASCII to the right. Stop and proceed slowly with <Space>. Other keys produce a faster display. <ESC> stops the display.

  In RAM, the hex dump can be changed with the editor. Empty positions are ignored. The listing can be scrolled up or down when editing.

- K 01 e000 [01 f000]
  (Kontrolle)
  Displays 64 characters of text per line from memory. Control characters (less than ASCII 32) will be displayed as periods. When editing, small and capital letters will be differentiated, periods ignored. Otherwise the same as "M".

- D fc 0008 [fc 0200]
  (Disassemble)
  Disassemble and list from $FC0008 to $FC0200 with machine code decoded to opcodes. Changes are unfortunately only on the hex words possible, since an assembler is not yet included in the program. This at least allows easy modification of some operands. With the help of a 68000 opcode table and some patience, small programs can also be entered.

  Since the structure of 68000 machine code is very complex, this part of MonST is sadly somewhat buggy. Attention should be payed to the following: It is not entirely inconceivable that a correct processor command will be incorrectly decoded (although I have not found any errors lately). If this should happen, please pass the information on to me. In addition, illegal opcodes will not always be recognized as such and flagged with "???". For example, code such as:

      MOVE.W D0,#1234 or CLR.B 061234(PC)

  is nonsensical, or illegal, but might not be flagged as such by the program. For this reason, the disassembler can get out of sync (for instance starting to disassemble on an operand instead of on an op-code), and display relatively long stretches of garbage. Scrolling the disassembler (as with "M" and "K") is useless because of this.

- >O {1,2}
  Switch printer protocol in/out
  0: Output to screen only
  1: Centronics port
  2: RS 232

- L filename.xyz, 05 0000   or
  L"filename.xyz" 05 0000
  (Load)
  Loads specified data file. You must always give a load address!

- S filename.xyz, 05 0000   or
  S"filename.xyz" 05 0000
  (Save)
  Writes the memory area to disk. If the file name already exist on the
  disk, you will be asked "are you sure?".

- @ [fil??ame.*]
  Shows a directory of the disk. If "@" is followed by a space, the
  characters which follows will be interpreted as a search mask. "?"
  wildcards a character, "*" wildcards remainder of filename or extension.
  If the command is given without a mask, "*.*" will be used (all files
  will be displayed). The display includes filename, size in bytes,
  and filetype as follows:

                            00 - Normal File
                            01 - Write-Protected
                            10 - Subdirectory, not file

  At the end of the display, the free allocation units of the diskette
  will be shown (each 1024 bytes long).

- @\directory\
  Specifies sub-directory or path. All further disk I/O will use this
  path (Loads, Writes, Directories). Return to the root directory with
  "@\".

- @B
  Specifies disk B: as the working disk (A .. E).

  The most important errors produced by disk I/O:

      -1 General error
      -6 Track not found
      -8 Sector not found
      -13 Disk is write-protected
      -33 File not found
      -34 Path not found

- F 01 0000 05 0000 41 42 43
  F 01 0000 05 0000 "Digital Research"
  F 01 0000 05 0000 44"igital "*"ese"61"rch"
  (Find)
  Searches byte-wise in specified memory. Hex digits and text can be
  intermixed. An asterisk outside of quoted text specifies a wildcard
  character. The addresses of matches will be given - use <ESC> to
  break off the search.

- F "-****(a*)" 03 0000 [03 1000]
  Searches for string in the disassembler listing from $030000 [to
  $031000] - "*" is a wildcard character. This example searches for
  all commands which use the "address register indirect with (negative)
  16 bit offset" reference mode. <ESC> stops the search.

- O 07 8000 08 0000 01 02 03   (512 KB RAM)
  O 0f 8000 10 0000 aa 55   (1024 KB RAM)
  (Occupy)
  Fill memory with specified long word value. If no value is given,
  the default is 00. Check out the above commands for a 512 KB and a
  1024 KB machine. The screen will fill with a fine point pattern -
  pressing the <Help> key will restore the display.

- W 05 0000 06 0000 07 0000
  (Write)
  Moves memory bank $050000 - $05ffff to $070000.

- = 05 0000 06 0000
  The memory bank starting at $050000 is compared with that starting
  at $060000. The position of the first non-match will be shown.

- #491520
  Convert decimal number to Hex. Max 2^32-1

- $00078000
  Convert 8-digit hex number to Decimal.

- %10101011
  Convert 8-digit binary number to decimal.

- ?z xxxxxxxx yyyyyyyy
  Simple calculator, where z = :
      + : 32 bit addition (2 8-digit hex numbers follow)

```
    - : 32 bit subtraction
    * : 16 bit multiplication (2 4-digit hex numbers follow)
    / : Divide 32 bit number by 16 bit number
    & : 32 bit logical AND
      : OR
    ! : EXCLUSIVE OR
```

- V
  (Vectors)
  Displays the vector table from low RAM ($0000 to $3fff). Addresses marked with an asterisk point to the BREAK-entry into MonST. The far left-hand byte gives the exception number. Stop display with <ESC>.

  Upon startup of MonST, the exceptions number 2,3,4,5,6,7,8,9, and 32 (buss, address error, illegal opcode, divide-by-zero, CHK-error, TRAPV-error, privilege violation, trace-mode, Trap #0) will be diverted to the register pointers. Should one of the "errors" occur, an attention character and a blinking cursor will appear in the lower left corner of the screen. The purpose of this is to avoid too-quickly destroying the contents of the screen.

  Pressing <ESC> releases the register display. A keypress produces an announcement of the exception number, and the processor register will be pointed to the location of the break. If it is a buss or address error, the information placed by the CPU on the stack will not be lost. It is this status word, holding the flags in the lower 8 bits, which describes the error more exactly, including the target address which produced the error and the last opcode acted on. A buss error can easily arise, if you try to access memory not implemented in hardware, or to write to ROM. You must be carefull not to set the stack pointer too low, thereby destroying something. Be sure to restore it to the appropriate value.

- TS 05 0000 05 0010
  (Trace Stop)
  The program will be started at $050000 and will break when $050010 is reached. This function uses the Trap #0 opcode, which is installed at the stop address before beginning execution. The machine instruction from that location is saved and restored after execution.

- TW [05 0000]
  (Trace Walk)
  Opcodes starting at $050000 (for example) are executed one at a time, with the help of the trace-bits in the status register. The screen is split into two windows: in the upper, the applicable processor is shown, and in the lower is the running program. The next opcode is displayed in the second-to-last line (pointed to by the current program counter). On the bottom line is a small menu, to remind you of additional possible functions:

<Space> Executes the next instruction
<ESC> Aborts
<C> Does the same as <Help> usually does (separates characters or graphics written to the graphics screen from other programs).
<S> Executes a sub-program in real time from beginning to end (to the RTS opcode).
<E> Does the same for an exception handler (to the RTE opcode).

For the last two, the stack pointer must be the same at the end of the sub-program as it was at the beginning. An example: By stepwise execution, you come to an error Trap #1, which calls GEMDOS. In order to run this program all at once, you press <Space> and see in the next-to-last line "BTST #5,(a7). This is the beginning of GEMDOS. Now you can press <S>, and GEMDOS will do its work undisturbed. The next command after the TRAP #1 will be shown. <E> can only used with the supervisor bit set. If no return address is on the stack, the program may run off into never-never land.

This all sounds very complicated, but with practice it goes smoothly.

"TW" works in ROM as well as RAM. Single-step execution lends itself especially to exploration of complicated calculations made by the CPU.

With the trace-bit set, a test program will not crash due to conflict in the status word, so that a command such as "MOVE #2300,SR" can be traced at your leisure.

- TB 05 0010 000a
(Trace Break) - parameters are address and word
A break point will be set at $050010 for fast step mode. Upon reaching the address for the 10th time, the program will be interrupted, and single-step mode will begin.

- TQ [05 0000]
(Trace Quick)
Fast step mode is only for use in RAM, and is used in conjunction with TB (see above). These functions lend themselves to convenient exploration of the operation of loops.

- TA 05 0000 0001 0000
(Trace Amount) - takes address, longword parameters
Starting at $050000, 2^16 machine instructions will be executed, though with somewhat limited speed. All sub-programs will be counted, as well as group two exceptions (TRAP's, CHK, Division by zero). Up to 2^32-1 instructions can be counted (4.3 billion). In addition, the program may encounter instructions which set the trace bit back! May be used in ROM.

c) The Disk Editor

The disk editor is invoked from MonST with "Z". It needs a 512 byte buffer, whose absolute address may be specified ($050000 is recommended, or somewhere in the middle of free RAM).

All disk I/O is done on drive A: (!)

- X
  (Exit)
  Exits the disk editor

- P
  (Page)
  Toggles the disk side, 0 or 1, with the result displayed.
  Use ONLY on double sided drives!

- B
  Change the buffer address (restart the disk editor)

- M
  Show the contents of the buffer. The contents may be edited.

- R 01 03
  Read sector 03, track 01 (hex)
  Only "R" and "W" specify the actual track and sector numbers.

- W 01 03
  Write the buffer contents to sector 03, track 01 (hex)

- +
  Read the next sector

- -
  Read the previous sector

In the disk monitor, scrolling text up/down is also possible. The sector buffer may also be accessed from the machine monitor.

---------- The End (Das Ende) ----------

  Note from translator:

      The above is a fairly literal translation of the manual for
      MonST as provided on BIX by Jim Omoura. The translator believes
      that the translation is accurate, but does not have the working
      program to check points of operation. I take NO responsibility
      for the accuracy of the above document.

John
The MAC presently has the software to do a very fine job of Desktop publishing.
The ST is up and coming, but does not yet have the same level of programs to
support your application. In my opinion, if you have the money, and need to
solve your problem, today, ... buy a MAC.

I received Uniterm, I linked the files together, I uudecoded it, I got the exact size it should be... The program does not run correctly. If there is no resource, it says no resource, bye bye, otherwise if there is a resource, the bee disappears and the program stops, no bombs no nothing, just a green screen with uniterm.prg at the top in t he menu bar region.

Anyone else have this problem, or has anyone gotten it to run?

Hi,

   I have had excellent experience with Easy-Draw. It is a full resolution-independent draw program, in which you work on a full page. It also allows you to mix text with graphics, using the full power of GEM. I have more than once used this program as a mini word processor to mix text and graphics. It is a very good desktop publisher. It is lacking a laser printer driver and support. Beats me why, I have met several people who would love to use it with a laser printer, and would pay. But it works fine with a epson printer. There also some other packages announced for release. I have tried the Graphic's Artist. I have to say, that program is slow and kludgy and not worth the price. For $149.95 (less mail order) easy draw is the top winner

Rick

[Hope this gets to the net... My previous message obviously never made it]

Is there any way to bypass all the sound synthesis hardware of the music chip,
and access directly the D/A converter ? The doc I have says nothing about this

possibility (I don't have the developer's kit..yet). Any help welcome.

I've been working on a program that will make extensive
use of GEM objects. I've seen a few comments in this
newsgroup to make me a little leery of the whole idea.

The programming is in Modula-2 using TDI's version 2.00a
(the developer's version). On a 1040 STF (mono).

The question are with regards to the MMRCP.PRG (the
Megamax resource construction program).

Has anyone (other than the original person - Simon Poole)
experienced the limitation of naming less than 200 objects ?

The problems that I have found with MMRCP (I've got Version 1.0):

1) The Merge... facility
   Used to (I imagine) merge two existing .RSC files - doesn't
   work. When I select this option - nothing happens.

2) The Info... facility

Used to provide some sort of information on object -
doesn't work. Again when selected nothing happens.

Has anyone else experienced these problems - or am I
doing something wrong - the documentation is pretty skimpy ?
In both case the 3 dots ... lead me to believe that
when selected I should get some sort of dialog box
or something.

>Since this may be only at our site, do you think you could re-send the two
>SHAR files to me? Thanx a lot...

Unfortunately, the error is due to a new (buggy) version of xmodem I just
wrote. Tonight I'll use the old version and repost the whole mess. Sorry
to all burned by this one ("...we can all cut down considerably the amount
of time and money we spend..." if some people would test their stuff before
they post it! :-).

While I'm here...

>I'll probably go ahead and assemble the .S file, but just out of curiosity,
>how do I edit a .PRG file?

You could do one of a number of things:

1) edit the sector on which the bad bytes reside using a sector
   editor (easy)

2) load the program into memory using a debugger, modify the
   offending bytes, re-write the file (kind of easy)

3) write a small program to read in the file (in binary mode)

and then re-write it (in binary mode) with the corrected
bytes (not so easy)

You can boot your ST with a RAM TOS image file disk in the disk drive and
it will "override" the ROM TOS. You can probably get such a boot disk from
a dealer, a club, or a BBS.

One of the nice things about frmtplus is that the disk format is recognizable
by TOS - you _can_ do such things as straight disk copies, etc., without
having to reboot with RAM TOS and frmtplus.prg in AUTO.

-Rich

I also tried the new version of UNITERM. The decoded length was correct, but
when I ran the program, I got 4 bombs, then back to GEM, which seems to be
running OK (this message is coming to you through the vt52 emulator, post-
UNITERM failure). If it is relevant, my system is a 1040STf with color.

Any suggestions?

Hello ST'er

I'm looking for a color screendump program on ATARI ST.
The printer is an DIABLO C150 Ink Jet.
The Interface Command looks like:
     ESC g n m (a)(n1)(n2)...(nm)
with
     n - represents the the color of image data and the pixel
         line number. (There are four pixel lines in each scan)
         0 - 3 : Represents black (0 = top line , 3 = bottom line)
         4 - 7 : magenta
         8 - ; : yellow
         < - ? : cyan
     m - represents the number of bytes that will be send as
         graphic data
     a - seperator "," or " "
  n1...nm - graphic data (8 bit bytes) with b0=LSB and Bit state:
         1 = print color dot and 0 = etc.

Any Program that do similar thinks would be appreciated.

Thanks
 mike.

Is it possible to write C applications under OS/9 and have them run under
GEM? This would be ideal. I suspect that the necessary library/glue
routines don't exist yet. Is this the case?

It's important that the ultimate output of the OS/9 compiler run under
GEM without any proprietary run-time support code.

Eagerly awaiting any reply,

-Eric

i'm getting ready to post the ST port for uE3.7i that really really works
on a b/w monitor (in two resolutions even!) but im going to stand pat on
sources, they go to dan lawrence (he reposts them every major release)

Two questions for the 'in the know'.

First, after installing an Atari Corp. 20 megger HD on my Atari520st (w/1 meg upgrade), I'm no longer able to acces the RAM disk. I'm using the RAM disk posted some time ago that was in ASCII hex format (640 byte .prg file). The hard disk seems to insist on being drives C: D: (conficts with RAM disk) and E:. I tried patching the hex code to read BSET #5,D0 to provide me with a drive F: ram disk. No go. Drive F: IS recognized but pulling a SHOW INFO says it's got 6meg available (not quite right 8^)). Anyone have this RAM disk living happily with an Atari Hard Disk? If so whats the correct formula? Who should be first in the AUTO folder? Is there a sequence of adding drive icons to the desktop? Maybe that's where I blew it?

Finally, saw MW C being advertised in this months Dr. Dobbs Journal. Does anyone have the package? A small review would be nice.
Do they provide a resource construction set?

Has anyone made any progress in translating the document file of the
recently posted Happy 68000'er monitor program? Surprisingly I was able to
figure out some of it (mostly the English words 8^>). I gave the document
to a relative of mine but her German is rusty and she know's zippo about
computers so many of the words won't be recognizable to her anyways.
Anyone else out there working on this?

>
> Rich Simoni

Yea, they aren't expecting first silicon on the 68030 until next spring or
so, last I heard. And sure you CAN get a '386 system, like the Compaq, today,
or a 68020 system (a "Turbo" Amiga is in the same price range). But instead
of comparing virtual performance, the actual performance should really be
compared. Today's MS-DOS based 80386 system, like the '286 systems that
preceed it, are still emulating an 8088, still have software than only
supports 640K or so of normally mapped memory, etc. You can add UN*X for a
better throughput. The "Turbo" Amiga, and Amiga with a 14.4MHz 68020 board
and some fast 32 bit RAM will work much better with the "base" system
software. Every progam that runs on the Amiga has the potential to use the
whole 4 Gigabyte address space along with the faster speed and wider bus.
Also, some run-time loaded Amiga libraries can be replaced with libraries
that take advantage of the 68020's additional op-codes, 68881 coprocessor,
etc. Still, programs will have to be recompiled with a 68020 compiler to
take full advantage of the processor, and of course, UN*X could be added.
I think a close comparison of these two systems would indicate the current
"off-the-shelf" winner in the Motorola-Intel battle, at least for the $3000
to $5000 price range. We'll have to wait for an 80386 based workstation, to
compare against a Sun-3 or the like, for the title in that price range.

I have a copy of the patent in front of me and I'm afraid that it is
quite general. They explain things in term of a general MMU that accepts
the address bus, uses direct address lines and indirect address lines,
a timing generator, and main memory. They then give a specific example
that they are running that uses segmentation and paging on the upper

address lines. They speak specifically about using dynamic rams (actually any rams that use row and column address strobes), and using the untranslated address lines before the translated address lines to increase the breathing room for translation. I'll quote the important section where he is actually telling what the invention is.

---------- begin quote mode ----------

Disclosure of Invention

An object of the invention is to minimize the delay incurred by a memory management unit in accessing a computer memory. The above object of the invention is realized by overlapping the delay time through the memory management unit with the access of memory. This is achieved by a computer memory addresses with row and column addresses and a memory management unit that allows low order addresses to pass directly into the row address of the computer memory whereas the high-order addresses pass through the memory management unit and enter the column address of the computer memory.

The system utilizes an address bus extending from a processor to a memory management means. The address bus splits memory addresses into pre-defined direct and indirect address segments. The direct address segments are fed directly to a computer main memory array of the type having rows and columns of control lines for bit storage elements which are located at intersections of the control lines. While the direct address segments are fed to either of the rows or columns of the main memory, the indirect address segments are fed to a memory management means which translates the indirect segments to a physical address. The translated indirect address segments are then fed to the other of the rows or columns of the main memory array, so that rows and columns of the main memory array are controlled by the direct address segments on the one hand and the translated indirect address segments on the other hand. The rows and columns of the mins array have connected driver circuits for enabling access to the storage elements. A timing generator is provided for strobing the row and column driver circuits with sequential pulses. While the direct address segmentsarrive first at main memory, and are strobed first, the translated indirect address segments arrive shortly thereafter and are strobed second, thereby permitting access to storage locations in main memory. The time between the two strobing pulses is used for indirect address translation, reducing memory access time.

In addition, the invention minimizes the address translation time of the memory management unit by using a high-speed static RAM (random-access-memory) for the translation process and by using the same RAM address lines both for address input and for accessing the entries of the memory management means in order to modify the translation.

---------- end quote mode ----------

This also looks, now that I have read it while typing it in, like they are also patenting using a high speed ram as the memory management storage device. This is even more general than people probably realized, but when I was looking into patents, the suggestion was to make it as

general as possible so you could better protect the heart of the process.

Anyway, if anyone would like a copy of the entire patent (6 pages) you
can send $2 to me and I'll mail you back a copy. This won't quite cover
the expense of getting it to you, but it will deter people who aren't
really interested in it that much and keep me from going broke sending
out a hundred of these. I'll pay for the envelope and the return postage.
Just send your mailing address to:

     Jeff Lee c/o School of ICS
     Georgia Tech
     225 North Avenue
     Atlanta, GA. 30332

I would suggest that you check your local library or maybe a college library
someplace close. This will save you $2 and a couple of weeks time.

Sorry if I've cross-posted to the wrong newsgroups.

I need the schematics for the Atari 810 disk drive. Can someone tell me
how to get them. (You know, give an address/phone number to call)

Thank you in advance.

I can't speak for Intel, and none of this should be taken as the opinion
of Intel, but...

...Motorola's "announcement" came in the same week that they chided
Intel for the 386's non-availability; the week that Compaq introduced
their box. Compaq must have gotten at least a few from us, since they
seem to have filled the channels of distribution pretty well, or at least
out here Computerland seems to have it, and Fry's is advertising it
(for a discount!) in their newspaper ads.

To put things in a historical sense, Motorola held the same kind of blitz
a few months after Intel came out with the 286, describing the 68020,
the 68881(?) floating point unit, and the whatever-the-number-is paged
MMU, all well before their general availiblity, or even their first
silicon. I suppose that Intel should feel flattered in that it seems

to me that Mot, in each case, has conceeded defeat: the 68010 to the
286, the 68020 to the 386, and that in order to maintain any kind of
market share, they have to have a media blitz, rolling out their newest,
half baked, family jewels. Its all pretty comic!

And what about the new family jewels? Should I feel vindicated that Mot
has finally decided that on-chip memory management is a good idea? And
what about performance? Why would a new, ultra-high end user choose
the 68030 over, say, the Clipper, or the MIPS chips, each of which
(if you believe the numbers) should exceed the 68030's performance (with
the promise of delivering more sooner) and are available, in some semblance,
today?
--
The above views are personal.

I've seen the future, I can't afford it...

I agree that the Motorola chips are nicer in many ways than the Intel chips.
But to say Motorola has "released" the chip is stretching things a bit. Not
only has the 68030 not been formally introduced as a product yet, but the
artciles I've read (e.g., Electronics, September 18, 1986) say volume
production is more than a year away. The 80386 is here now, and actually
has a system available (Compaq) which uses it. In other words, it's not
really fair to compare that which Intel has now with what Motorola will have
in a year. A more fair comparison is between the 68020 and the 80386.

The TT will be a UNIX machine and cost several (?).
It is NOT an add-on to the ST - it's just the opposite!

The 32081 chip, 6 MHz version, quantity one, costs <0.

A working board with it could probably sell commercially
for about 00.

If all you want is fast FP, what would you get?

In case you don't know, many people who pay money for disks that
contain shareware think that they have payed for the shareware,
and thus don't have to send in any additional money. From the
posting I was responding to, it sounded like RR was the only
thing on those disks that was not free, and that there were
only two or three disks. $40 seemed a little high for three
disks of free stuff unless the seller of the disk was selling
Red Ryder.

I am in need of an editor, any, which supports 50 line mode on a monochrome
monitor for the ST. So far, most TOS editors work fine, but none of the ones
I have support 50 lines. I had STEDT, and the one that comes with Personal
Pascal. Anybody know? Help would be greatly appreciated.

Eric, you don't seem to realize: OS9 'IS AN OPERATING SYSTEM'. It's modules are all re-locatable, use OS9 I/O calls, and in short do not 'fit' onto GEM - NORMALLY. But I seem to recall (when I used my trusty old 6809 a lot more) that the assembler (and at least one C) could gen 'Native' code. But this made testing a pain, as you had to re-boot the old OS, run your code (if you were lucky you had a debugger), and then re-boot OS9 to re-EDIT, COMPILE, LINK... sad. In short, you stayed in OS9. But then the 'native' OS on the Tandy Color Computer with 64K (there I've admitted it!) was BASIC (yech), so it wasn't worth it.

   In short: When you boot OS9, you can still run BIOS, but you kiss TOS, and GEM goodbye (I think). And as you say, I doubt OS9 has the libraries. Now, weather the ST version of OS9 has a SIMILAR type of windowing and menu system... I don't know, havn't seen the ST version, and I don't know how far it has gotten in it's evolution. Comments anyone?

The next file that I will post is the source code to version
1.1 of my SPELL program. I have added one enhancement to the
program:

When SPELL encounters an unfamiliar word, the user is given the
option of inserting the word into the dictionary, or not inserting
the word.

With version 1.1, if the user chooses NOT to insert the word into
the dictionary, the word is considered as being correctly spelled,
and if the word is encountered again, the user is not asked what
to do with it. The word will not be saved in the dictionary, of
course.

This should be helpful when there is a word in the document

Let me try again:

This should be helpful when there is a word repeated several
times in your document that you don't want to insert into the
dictionary.

How to get the executable file for SPELL:

I regret that I am presently unable to successfully send executable
files to my VAX. If someone with OSS Pascal would be kind enough to
compile SPELL 1.1 and send the uuencoded binary to this net, I would
be greatly appreciative!

My next project will be to write a program that gives the times of
moon rise and set, sunrise and set, solar and lunar eclipses for an
observer's location. I hope I can find the time to write it! However,
as a graduate student, I am very busy this semester...

Thanks,

Eric Bergman-Terrell (CSNET Address terrell@ohio-state)

[]

Here is an improved version of my X-Y plotting program.

Note that I took the log-scale stuff out.  That's because I didn't
like having to link to the math lib all the time.  Instead, take logs
before you call plot().

I added a settable plotting area with VDI clipping, and also a cooked
call to v_pmarker.  You are still limited to one plot at a time as long
as you use this simple approach.

Personally, I am AMAZED how fast this thing runs!
```

If you wish to have a RAM disk living happily with an Atari 20mb
hard disk, you have to "install" it as drive F in addition to having
it come up as drive F:.

I've gotten a ramdisk to work with a hard disk this way.

This is a known problem. It was discussed a while ago, and i seem to
recall that thre was no general agreement on what should be done. I know
that ST-Talk installs its own interrupt routine (thats how it avoids
the garbage characters that the Mfp insists on spitting out whenever
you do a Rsconf(), even after explicitly disabling the transmitter
in the Tsr(bit 0). The way i worked around this problem in xmdm, was to install
a large (32k) buffer of my own using Iorec(). Since then the problem has
never re-appeared. I use xmdm at full 9600 baud almost all of the time.
Hope that helps.
bammi
PS: if you know how to stop the MFP from spitting those (3) characters, i would
lve to know. Currently, in xmdm, i send three ^H's following a rsconf to
get rid of them. Also, with the large rs232 buffer in place, i put flow control
completely off, and have never lost a character at 9600 baud.

X      Here's a bug for which I still need a solution.  GEM does not always seem
X to report the release of a mouse button.  I've tried evnt_multi(), vq_mouse(),
X a  routine  that  steals  the  mouse  interrupt  and checks the buttons before
X handing  things  back  to GEM, and a few other things and in all instances the
X status  returned  is not always correct.  It is correct if you move the mouse,
X which  leads me to think that the mouse packet doesn't always get sent (which,
X of  course, would not be a GEM bug).  John Feagans at Atari said they were not
X aware  of  this  problem;  however,  several other developers on the Atari BBS
X reported the same thing.  It happens on the Desktop sometimes: you click on an
X option  but  nothing  happens  until  you  move the mouse.  I hope someone has
X solved this one.

Fm: Stephen Mehalek 73277,2557 To: SYSOP*Dave Groves 76703,4223

The modulus operator that comes with VDIBIND library is incorrect. The lrem.o object module contains 144 bytes and produces results of zero when it is used to give the remainder of long integers. The fix is to take the lrem.o module from the GEMLIB object modules and move it to the VDIBIND libraries. Use the AR^ AR68 utility routine to do this. This bug is not a GEM bug, but most people owning the developers package should know about this.

X Fm: David Beckemeyer 74236,625   To: Ric Clayton 73317,1350
X   Ric, assuming there isn't a simpler, plain old bug, in your program, it
X looks like you may be running up against the classic GEMDOS getting confused
X bug.
X
X   I have seen this sort of problem, (GEMDOS unable to open, or create a
X file for no apparent reason), and I have traced it some internal data structure
X handling bugs in GEMDOS. It seems than GEMDOS keeps a copy of the directory
X tree structure of each disk, and as you access directories continually adds to
X this data structure.   The idea is to make file accesses faster by avoiding
X reading each directory in the tree of a file spec whenever a file is accessed.
X
X   So far so good, but under some circumstances, which seem to relate to the
X number of directories accessed (across all drives), and I think also related
X to floppy disk media changes, this internal GEMDOS data structure gets messed
X up, and GEMDOS doesn't know where to put the next link in its structure, and
X goes out to lunch forever.
X
X   I don't know the whole solution to this problem, b but I have been able to
X reduce its frequency by making an undocumented BIOS call at certain times,
X which seems to force GEMDOS to free some internal memory. I found it by
X catching the desktop making BIOS calls. I don't have the code in front of me,
X but maybe John Feagans @ Atari could help? If not, I'll look it up and leave
X you a message. - david

X
X Fm: Ric Clayton 73317,1350   To: All
X   Hi there, I have written a program to backup files from my hard disk to a
X floppy disk and have run into a problem I can't seem to get around. The
X program is rather simple; it just copies files from a source directory to the
X same directory on a designated floppy drive, creating directories as needed,

X using GEMDOS calls. Nothing fancy, just regular DOS type file copies. So the
X program goes chugging alone, happily copying files and all of a sudden gets an
X "file not found" error (-33) when it tries to open the Source file for
X reading, the name of which it just got from a directory scan! After this
X occurs, GEMDOS seems to be completely dorked and strange things start to
X happen, requiring a re-boot to restore it to normalcy. It doesn't always
X happen, and when it does it's not always in the same place. Sometimes I can
X get through a whole 5MB partition with no mishap. Sometimes I can't even get
X through the files in the root directory. I have gone over and over the code
X and can't find any error that would cause this. However, I'm new to both the
X ST and 'C' programming environments and may have made some false assumptions,
X so I'm asking for any help I can get. I would be glad to upload the source
X code if anyone would like to give it the go over. The program doesn't use
X GEM, just gemDOS (or is it TOS?). (I've compiled it with Megamax-C and Mark
X Williams C and get the same error. Though I haven't tried Alcyon-C yet.)
X
X   Thanks in advance for your help.

X Fm: Jim Needhan, DRI 76703,1064   To: Corey Cole 76224,66
X   I assume the confusion is with "mouse" calls and the such... The AES
X should always be used rather than the VDI when making mouse or other hardware
X calls. I have heard the complaints about speed but I do not fully agree with
X those programmer's with the concerns. I do realize that there is a speed
X "hit" but what is gained is a program that is more reliable and more portable.
X The AES cannot keep track of what the VDI is doing so by going through the AES
X the "system" is aware of what is going on.
X
X   Of course, you may write directly to the VDI and in graphics display
X calls etc. it is the correct path, but, for windowing, mouse control, etc.
X it is better from the DRI point of view to go through the AES.
X
X   Portability? There will be GEM available for other environments, and
X announcements will be made as appropriate, so don't lock yourself out if it
X isn't necessary.

X
X Fm: Corey Cole 76224,66   To: Jim Needhan, DRI 76703,1064
X   Jim, I guess I didn't make myself totally clear. When I was complaining
X about "speed hits" when using the AES to read the mouse, I didn't just mean
X response delays (although those are bad enough). We're talking actually
X failing to recognize events -- for example, if the user presses the left mouse
X button in an application using graf_mkstate, the application will not be
X notified unless the button remains depressed for a sizable fraction of a
X second. I believe the same is true with evnt_multi. This behavior can be
X seen in many GEM applications (Megamax editor, DEGAS, etc.) -- user has to
X hold down the button for about a second to get a new cursor (or whatever).
X Highlighting (in FLASH, megamax editor, my word processor until I went over to
X vq_mouse, etc.) also "feels" jerky to the user because the program isn't
X immediately notified.
X
X   At the GEM seminar last year, I was told that evnt_multi does not wait
X the double-click time if the mouse moves more than a pixel or two. This
X
X

X   #11000-#GEM Bug List   Page -7-
X
X
X
X
X   #11000-#GEM Bug List   Page -8-
X
X
X simply doesn't seem to be the case (it should be), in my observation. In
X general, mouse events have a "clunky" feel to the user, which tends to hurt
X the "feel" of the entire application. Sorry to drag this into the ground,
X just not sure how clearly I'm stating this! -- Corey

X
X Fm: Mark Skapinker (BI) 76703,207 To: SYSOP*Dave Groves 76703,4223
X Here are a few 'goodies' we know about:
X
X First some bugs:
X
X -If you use a regular "form_do" in a desk accessory, you may find that
X your keys 'fall through' to the application, so be prepared to write your own.
X Falling through means that if you have a desk accessory on top of a word
X processor for example, keys pressed during a form in the desk accessory would
X be picked up and used by the word processor.
X
X -Evnt_timer is a very dangerous call to make from a desk accessory; it
X sometimes causes the entire program to freeze up . Regarding timers see the
X following message from Chris.
X
X - The system exception handler has some bugs. (See the following message
X from Chris)
X
X -Appl_play and record do not work without an ROM patch from Atari.
X
X -Alcyon Compiler problems. Appl_init returns the wrong value (always
X returns 1).
X
X -The documentation for Vex_motv is wrong - it requires a jump to the
X saved address to update the driver.
X
X
X Some things to remember:
X -Before doing an fsel_input call, and before any I/O, make sure you have
X set path names (A: is not good enough, it must be A:\), or be ready for a
X freeze.
X
X -Form_alert strings can only be about 30 characters per line.
X
X -You should modify the source of form_do (form_keybd) to change
X underscores to dashes; underscores blows your application out of the water.

#: 11204 S2/GEM Support 08-Sep-86 13:20:55

Fm: Mark Skapinker (BI) 76703,207 To: SYSOP*Dave Groves 76703,4223
There are 2 serious bugs related to desk accessories. Both were reported to Atari months ago.

1. EVNT_TIMER is flaky. The timer event will not always return when called. This seems to happen most often when there is heavy disk activity, but not always. If you do an evnt_multi() with messages and timers, the timers will eventually hang up, but if the accessory receives a message, the timers start working again (for a while). We call this burping the timer. As a programmer, this means that you must find an alternate way of releasing control (it isn't easy). That's why some desk accessories degrade the system performance so much. This bug has been ported from the IBM PC version of GEM.

2. The system exception handler has one or more bugs. If an application generates a system alert (drive not responding, insert your new A: disk, etc.), any desk accessory that is running is not stopped. That is, if you have an accessory buzzing along waiting for evnt_timers (which you shouldn't), or mouse movement events (actually any evnt_ function has this problem), the multitasking of the desk accessories is not turned off while the alert is presented. I checked this out with an accessory that woke up constantly and wrote a counter to the screen. As soon as the alert is cleared, the desk accessory, then the application bomb. I suspect it's because the accessory gets running in supervisor mode and messes up the super stack or something like that. The same thing can happen in a one drive system in another way (this is probably a separate bug). If the desk accessory reads from drive B:, and the system alert is generated to swap diskettes, after the alert is cleared first the desk accessory then the application will bomb. We've even seen it bomb the GEM Desktop.-- Chris Bailey (Batteries Included)

Fm: Rich Plom (Intersect) 73307,1676 To: SYSOP*Dave Groves 76703,4223
You want bugs, use the file selector. It is one of the most flawed things in the system. You can crash it two ways, put the '_' in the path. Or, you can just leave a disk out and wait two times for it to give the abort continue error, after that booomb! Also, when you have a single drive system and you try to treat drive b as disk b, he really gets strange.

X   I have noticed the following bugs in GEM: Bug series #1: (AES object
X library section)
X
X   In the TEDINFO structure, te_pvalid field, the following validation
X characters DO NOT work properly: 9, A, a, N, n, P, p, (all except F and X).
X The bug occurs when a form_dial is called with an object containing any of the
X
X
X
X   #11000-#GEM Bug List   Page -9-
X
X
X
X
X   #11000-#GEM Bug List   Page -10-
X
X
X above characters in the PVALID field. If the user types an underscore "_" on
X any character position (except the last), the system promptly "bombs" out.
X The bug with the "F" character in that situation was fixed in ROM TOS and the
X "X" character never had this problem (to my knowledge).
X
X   Also in the TEDINFO structure, the te_txtlen and te_tmplen fields both
X contain   the   length+1   of   their respective strings, contrary to the
X documentation.
X
X   Bug series #2: (GEMDOS section)
X
X   Hard disk file WRITE time increases by roughly 1 second for each megabyte
X stored on that drive (partition, whatever).   This is probably due to
X unspeakably slow FAT search code (it takes about 450 times as long as it would
X using two simple 68000 instructions to search a FAT sector).
X
X   Dfree() command takes "next to forever" on the hard drive.
X
X   It is somehow possible to get a folder (on the hard disk) that is
X impossible to delete, even though it's empty. - Ken Settle [76556,753]
X
X
X   #: 11268 S2/GEM Support 09-Sep-86 11:42:38
X
X Fm: Ken Settle 76556,753   To: Ken Settle 76556,753
X   Bug series #3: (GEM Desktop section)
X
X   SOMETIMES when you close a directory window and re-open it from another
X drive, the window decides to exactly cover up the top window on the screen.
X This has been a major annoyance causing me to be paranoid about closing a
X directory window. It seems to be very random (as all truly good bugs are).
X
X   Changing resolution and/or colors can really screw up the desktop when
X you return to it. It should be Desktop's responsibility to make sure these

X conform to the current defaults. Desktop should also automatically set ALL
X DESKTOP.INF defaults on power up, and allow ANY application or accessory to
X have access to/modify these defaults (palette, key rate, RS232/Printer
X setup).
X
X Desktop should be hardy enough to survive a "close workstation" call by
X an application, without losing it's "pull-down menu" capability. This might
X allow VDI to be used in any resolution as dictated by the application, not
X desktop.
X
X It should be possible to abort a multiple-file COPY or DELETE operation
X at any time using the mouse and/or keyboard.
X
X Bug series #4: ("TOS" section)
X
X An error box stating "TOS ERROR #35" means nothing to most people, what's
X the real message?
X
X Bug series #5: (AES/VDI section)
X
X The dot-pattern in the move bar of a window can get screwed up by a
X
X

X
X Fm: Tom Jeffries 73717,2261 To: Jim Needhan, DRI 76703,1064
X There's an old rule of thumb- if one person tells you you have a tail,
X don't bother to look. If ten people tell you you have a tail, you'd better
X take a look to see what's going on. Actually, I think most of us look when
X one person tells us we have a bug. There is a whole series of problems with
X reading the mouse which include: slow and inaccurate reading of the mouse
X buttons, especially from the AES, evnt_multi() will not read both mouse
X buttons (as far as I know that's not in the bug list yet, we should add it),
X mouse button releases are not always recognized, etc. etc. etc. I must
X admit I'm getting a little tired of DRI and Atari trying to blame these
X problems on bad code. Too many developers are having the same problems for it
X to be bad code. In an earlier note, you defend the slowness of evnt_multi.
X If it really were accurate, I might go along. However, even if that were the
X case, it is hard to ignore the fact that the Mac, which also has to read
X double clicks, feels much less clunky than the ST. GEM, like all operating
X systems, has some problems. Actually, if you compare it with MS-DOS, which is
X much simpler but also has lots of bugs, you guys at DRI and the folks at Atari
X did a terrific job, especially considering the time it took to get the machine
X on the market. No purpose is served, however, by trying to blame bad code for
X problems that are real and don't seem to be getting solved. I don't mean to
X cause offense- but since we have the benefit of having some of the people who
X wrote GEM online, I would like the discussion to be at a realistic level.
X Thanks,
X
X Tom Jeffries

X         Bugs in the ST Resource Construction Set
X
XThe RCS originally shipped with the Atari Developers' Kit did not receive
Xadequate testing, and as a result contains a number of bugs, two of which
Xare show stoppers.  Due to numerous questions on the SIG, and Tom Hudson's
Xsuggestion, I am documenting them here.  (The statements here are my
Xown, and have nothing to with Atari or DRI.  Use them at your own risk.)
X
XBug #1)  The RCS does not work properly with color systems.  The character
Xsize used is incorrect, resulting in objects which are twice as high as
Xintended.  The only solution is to use the RCS with a monochrome system only.
X
XBug #2)  When using icons or bit images, the RCS may produce a resource file
Xwhich causes an address error on the 68000.  This occurs because the RCS
Xis not forcing the images to an even byte boundary.  Since the images are
Xwritten immediately after strings, any resource with an odd number of bytes
Xin the string will suffer from this problem (if it contains images as well).
XTo work around: make a copy of the resource BEFORE adding ANY images.
XThen add the images and attempt to save the resource from the RCS.  If you
Xget an error, restore from your backup, add one byte to any string, and try
Xagain.  Whenever editing ANY string, do the same thing.  ALWAYS keep a
Xbackup copy!  By the time the RCS bombs, your resource is history!
X
X"Feature" #3)  The icon format expected by the RCS is rather obscure,
Xshall we say.  This happened because the RCS expects to find icons written
Xby the GEM IconEditor, which was never ported to the ST.  If you want to
X"roll your own", an example of the correct format follows.  You may change
Xthe hex size values, and add or subtract data lines to suit.  You must
Xmaintain the EXACT format of the data lines.  Easiest place to go wrong:
Xthere is one and ONLY one padding blank at the end of each of the hexadecimal
Xdata lines.  It's important!
X
X/* GEM Icon Definition: */

Does anyone know how to use these functions? In particular, is it
really possible for multiple applications to exchange messages? If so,
how does one get the ap_id to send to?   An example would be helpful.

Thanks,

Denny

My manual doesn't say anything about 03 = both buttons, but I have tried 02
for the right button with no success. I admit that I've been using
evnt_multi, not evnt_button. Could this be why it's never worked for me?
If so, I maintain that the gripe is valid. Most programs are going to have
to wait for keystrokes and menu events as well as button events... If I'm
wrong, I withdraw my remark... (BTW: what does the F stand for in RTFM?)

From the 'I said it couldn't happen to me' dept:

Turned on my 1040 this morning, the power light went on, the disk select
light went on, the disk made one light 'putt' sound.

No seeks, no screen, no nothing. I think my warranty *just* expired.
I have no idea where to start trouble-shiooting, and besides, although I
can use a multimeter, I've never laid hands on a logic probe.

So this is a last resort before I phone the dealer and way (?) months and
pay (?) dollars to have them fix it.   Does anyone have a quick suggestion
or 2? I'm not ENTIRELY all thumbs with a soldering iron, but that's about
it. Please reply direct, as I'd hate to clutter up the net (unless it's
something you think one and all should know.

I should also mention that we've been experiencing some VERY nasty weather
here, (thunderstorms) BUT:
- I haven't had it powered on during a storm,
- I've had the modem turned off (I read something in earlier postings),
- Everything connected to my computer is plugged into a 'power bar', and I use
  the switch on that to power everything up and down at once, except the CPU,
  which I switch on later/off 1st.

Given the above, what is the likelihood something nasty fried a chip? I expect
that was it *sigh*... Some spike came in over the phone line, right!? In the
future, should I even go as far as to remove the RS232 cable from the modem or
the ST while the system is not in use?   Or wire up some switch, maybe even
solenoid driven, to bypass the modem when I power off the ST. Why doesn't the
modem or the ST come with such a switch? I wonder which of the phone lines the
ugly critter used to carawl into my system? Ring, ground, or ?

>
>   Stephen Walton, speaking for myself

Try again, just because there is a 40MB/s bus transfer rate *does not* mean
that there is a 25 ns bus cycle! If the processor transfers 4 bytes/xfer,
then the bus transfer rate will be 40 MB/s on a **100** ns bus cycle time.
If the transfer is 2 bytes/xfer then the bus cycle would be 50ns, etc.
Additionally, your assumption does not take into account capabilities such
as those on the 68030 to support new DRAM technology (page mode, static
column, nibble mode) which allows the transfer of 4 long words (16 bytes)
in as little as 5 clock cycles.

I'll announce a new bitnet file server at SILMARIL@FINHUTC.BITNET.

For more info try the following command (VM/SP):

```
  TELL SILMARIL AT FINHUTC GET ST PROGRAMS
```

Others: try your favourite //-command.

(Note: File server is located in Finland; so extensive use from US
is not necessarily a great idea).

One of the first programs available from SILMARIL is a port of the
game of LARN. Try:

```
  TELL SILMARIL AT FINHUTC GET LARN PRGUUE
  TELL SILMARIL AT FINHUTC GET LARN HLP
  TELL SILMARIL AT FINHUTC GET LARN FOR
  TELL SILMARIL AT FINHUTC GET LARN MAZ
  TELL SILMARIL AT FINHUTC GET LARN SCR
```

Total size is about 250k.

Author of this port is Pasi Turtiainen (my brother). I'll
forward thanks to him. (Buggestions & suggestions are welcomed,
too).

Feel free to send all your PD programs to me (preferably UUENCODED,
remember one additional character at the end of each line).

Esa Turtiainen

>>machines but they need a multi-tasking O/S SOOOOO badly.

Beckmeyer has just started shipping MT-CSHELL for the ST which is
a MULTI-USER and multi-tasking OS that has a UNIX like flavor. It
sits on-top of the TOS file structure and so does not have a 'chown'
and other utilities but it feels a lot like Berkeley UNIX otherwise.
It can run one 'gem' program on the regular screen but other TOS
programs can be run from the serial-port user and the console user.

Summary: right button is just as good as the left

The fact is, the you can wait for the right mouse button just as well as
the left. What you can't do is wait for "EITHER the right OR the left
button." If you study the semantics of the evnt_button call, you will see
why.

What you CAN do is substitute your own button handler, using the well-defined
GEM interface (rather than mucking with hardware interrupts). See the
VDI call "Exchange button change vector" and Appendix E, "Processor-Specific
Data."

Once you get the hang of that, your control of the mouse buttons can get
as fine as you like! Imagine: long-click vs. short-click, Left followed
by right as different from right followed by left... The possibilities
are endless! :-)

At the risk of starting a religious war, I would appreciate any MAIL on
the best system to start an eight year old on which also has enough
power to be useful to me and my older children. I think this boils
down to the Amiga, Atari ST and the Mac.

The user interface should be very intuitive and easy to use. There
should be interesting games and graphics programs as well as powerful
software for editing term papers and other documents. I would want
communications software to call my Unix system at the office and
transfer files or run programs. It goes without saying that a Unix
compatible C compiler would be required eventually and with that there
should be a good development environment. I would really like to see a
debugger like the dbxtools program I recently saw running on a Sun --
Wow! An actual Unix port would be super down the road a bit.

I don't need much to start with, but later we might want a hard disk and
more RAM. I have heard about some neat stuff for digitizing and
manipulating photographs and video signals. Who runs that?

I would most like to hear from people who have experience with two or
all three of these machines rather than just one. I would appreciate
mail since I don't usually read these groups.

Thanks for any help you can send.

Does the "Turbo" Amiga have an MMU? If not, then adding UN*X is going
to be very hard. Adding unix to the Compaq 386 box will be very easy.

Summary: Motorola's continual announcements

In re: Motorola's continual announcements . . . is it fair to compare the 68030 to the 80386, etc.?

Yes.

Firstly, it is clear that Motorola's architecture is a lot cleaner than Intel's. Certainly their chips may be a year or so behind Intel (i.e. 68020 and 80286, 68010 and 80186, etc.); but their chips are far superior. Even if you insist on comparing the 68010 to the 80286 it is not clear at all that the 80286 wins hands down; the '010 has an architecture more well-suited to implementation of multi-level interrupt multitasking systems. The fact is that for implementation of real systems the 68010 in many cases is a far more appropriate choice than the 80286. (about Unix implementation, see BYTE article last month.) And of course the 68020 is far and away the superior chip compared to the 80286, and the '020 has been available in real computer systems for some time. From this point of view it seems reasonable to compare the '286 to the '020 rather than the '010, and here the comparison is clear. '020s are used (as you all know) in Sun workstations, TurboAmigas, etc. '286s are used in ATs. There is really no comparison between the two classes of machine.

Another important point to make is that operating systems implemented on the 68000 series chips will run fairly well on the higher-grade chips; UNIX, AmigaDos/Intuition, Mac Operating System, ST GEM/TOS, et cetera are all capable of taking advantage of the higher-level chips' capabilities (especially UNIX and AmigaDos/Intuition), although some optimization wouldn't hurt. From the point of view of the Intel chips, the 8088-based MS-DOS is nothing more than a kludge on the 80286 and 80386; for that operating system to take advantage of those chips a complete re-write must be done, and is in the process of being completed as we speak. This new operating system however will most likely be incompatible to a great degree with the old, 8/16-bit MS-DOS and will contain major bugs for some time. AmigaDOS/Intuition has been running on the 68000 for about a year now, and Unix implementations for the 68000/68010 chips have been floating around for at least 3 or more years. To compare the 80386 with the 68020 is absurd; the '020 has been around for some time now and has a lot of debugged software/operating systems running on it; the '030 will inherit that software and blaze with it whereas what will the '386 do? Run character-stream UNIX and 640K MS-DOS?

-Mitsu (hadeihi@husc4.UUCP)

P.S. BTW, have you guys heard about the 78000 (!?) See Nanobytes in the latest BYTE (the //GS issue). This is a RISC uprocessor with a rated speed of 20 (VAX-equivalent?) MIPS . . . this kind of speed totally blows away the RT PC (note: the RT PC performed just a hair

better than an PC AT in benchmarks . . . see PC World or PC magazine
of a month ago. . . not very impressive . . .)

I realize that OS/9 is an operating system unto itself. The point is that
GEM and VDI are not: they are acually libraries. It's still not clear

to me whether they are in ROM on the ST or linked in with every application,
but, regardless, OS/9 should be able to talk to these libraries. Theoretically
code linked to access GEM/VDI (if such libraries existed) would still run
if the program were run under TOS. The I/O, on the other hand, is more
troublesome. I wasn't totally serious in asking such a thing, just wishful
thinking.

Isn't it interesting that Amiga has not had any problems with Apple?
(or have they and I just haven't heard about it?). The point is
that it is possible to make a reasonable user interface for a mouse
based windowing system without copying the "look and feel" of the Mac.
Why couldn't DRI go to the trouble of doing this?

From what I have seen, it looks like Apple looked at the Xerox stuff
as a source of ideas. DRI appears to have looked at Apple and tried
to look as much like them as possible. There's a difference.

Unfortunately, Bruce then posted a followup article stating that multi-tasking GEM would not be released this year and he should not have mentioned anything about it. Apparently, they are working on it, but have no firm time schedule for its release.

I hope that Atari will purchase it and release it when it becomes available. If not, then DRI would be smart to release it themselves, since the market for it would be HUGE!

I was thinking about eventually getting some roms for my 520 . Unfortunately, Ive heard that some packages only work with one version and not another . Being in the UK , I would prefer to use the UK version . Is it possible , short of taking the roms out , to disable them so I can load another version from disk ?

Are there any *cheap* ramdisk utilities around ? If you know of any , could you send me details .

Thanks in advance ,

There is a bug in SNAPSHOT.ACC which makes it impossible to take pictures of
a GEMDRAW or EASYDRAW screen.
If you use Snapshot/0.14 with resident GDOS.PRG, you only get "empty" pictures.
This is especially annoying as the double WORDPLUS - EASYDRAW would have been
an excellent documentation system.
Last weekend I found the reason for the "empty" pictures.
It is a call of the VDI copy raster routine (vro_cpyfm) with a handle being
constantly 1. This works if the screen is the only VDI device.
But with GDOS you can have other VDI devices and the physical device handle
number of the screen has changed.
If someone is interested in my modified version of SNAPSHOT, I will post it.

Concerning VDI devices I have a few questions to which someone perhaps has
answers:

1) Is the physical device handle number identical to the device identification
   number used as input for the open workstation call ?

2) How can I see, which workstation is opened ?

3) Who opened the screen workstation first and which device id number is used ?

4) Why does the ASSIGN.SYS for EASYDRAW use 4 device id numbers for the screen ?

Thanks in advance.

I thought I'd pass along some experience I had with a software package called Regent-Base. I ordered this program about two weeks ago, based upon a recommendation that this software had a good GEM interface and was fairly powerful.

The manual comes with a classy cover, but the internal documentation looks like it was quickly made, with numerous typographical errors scattered throughout the manual. They couldn't have used a spelling checker on it, although I think they have a product called Regent Spell!

After studying the manual for many hours, I wrote my first application. I was able to design a GEM-appearing screen without too much difficulty, and started on the report generation phase. I soon ran into unexpected error messages that didn't apply. In fact, I soon uncovered about about six problems, ones that severly impacted my application.

So, refering to their documentation, they say to contact them from the hours of 10 am to 2 pm for help. But they neglected to list a phone number, and I had to call information for it. On my first try, all I got was a recorded message. On my second try, the next day, someone answered who couldn't help me. In fact, he said, only "Frank" could help me, and Frank wouldn't be back for a few days. Well, several days later I called again. Again, a recorded message. I left my name and phone number. No reply. Three more days I called, all during their service hours, and always getting the same recorded message.

I'm now wondering if they are still in business. If they have a staff, it must be extremely small if only one person in the company is capable of answering technical questions on the product. I'm sorry I bought this product, and can only relate these experiences to others out there who are wondering about purchasing it. My recommendation is to avoid Regent Base until they come out with a less buggy version and until they can muster a staff to answer the phone.

Gee, that was to much to ignore...

Can anybody point me to the numerous powerful multi-user super-boxes that
are using the '286 or '386 (AT doesn't count since it is actually used
by single users, and in 8088 emulation mode, primarily)? As far as I can
tell, designers that are not REQUIRED by their employers to use Intel
chips have long used the 68K family for that purpose!

If you want REALLY high-end computing power, you get a CRAY and such.
If you want a real big bang per buck, you get a 68K personal machine.
Unless, of course, you only feel comfortable in the crowd, the crowd
that will use 8080 software forever (they think).

- Moshe Braner

BTW: the ST + 32081 math coprocessor beats (for number crunching) the
portion of the power of the VAX I work on that actually labors for me.

Price? still < $1000

Up to now I have always hated intel chips. In general they are *so*
contorted/poorly thought out, (some would even say buggy). Up to
now that is. I'm ready to to believe in 80386's. Lets face it, the
lack of *usable* memory management for the 68000 is laughable. The
68020 mmu is still vapor-hardware. When it finally arrives, one gets a
chip that has to have *lots* of logic around it just to allow it to
work in the same circuits that the 68020 used to work in. It will run
much slower than the 68020 however.

Remember, the 68020 is in the same generation as the 80386. (lets hear
some applause for intel.)

Depends entirely on the foresight and ability of the systems programmer (about
whom, in most cases, I have grave doubts). Mac OS dies on anything higher than
a 68000...
>
>'386 do? Run character-stream UNIX and 640K MS-DOS?
You betcha. At the same time. Quickly. With graphics additions as hardware/
software becomes available.

I have said before and I will say again now - religious chip wars are useless
and S*T*U*P*I*D. All of the debate and struggle gains you not one thing.
Personally, I'd rather be aware of and comfortable with as many of the
different architectures/chips/systems available - it makes me that much more
employable (and that much more affluent). When I look at what power I have
sitting on my desk now, IBM *OR* Amiga or whatever, and compare it with the
most powerful computers available when I started in this business, I find it
really hard to bitch too much about a chip - even, god help me, the 6502.

> First, after installing an Atari Corp. 20 megger HD on my Atari520st (w/1 meg upgrade), I'm no longer able to acces the RAM disk. I'm using the RAM disk posted some time ago that was in ASCII hex format (640 byte .prg file). The hard disk seems to insist on being drives C: D: (conficts with RAM disk) and E:. I tried patching the hex code to read BSET #5,D0 to provide me with a drive F: ram disk. No go. Drive F: IS recognized but pulling a SHOW INFO says it's got 6meg available (not quite right 8^)). Anyone have this RAM disk living happily with an Atari Hard Disk? If so whats the correct formula? Who should be first in the AUTO folder? Is there a sequence of adding drive icons to the desktop? Maybe that's where I blew it?

No. The problem is that the ramdisk drivers only intercept calls to drive 3 (= D:); simply patching the BSET is not enough. I have disassembled the whole thing and am in the process of rebuilding it in a slightly more general way. (For example, I prefer that it get the ramdisk size from a file.) I'll post it whenever I get around to finishing the job.

> Finally, saw MW C being advertised in this months Dr. Dobbs Journal. Does anyone have the package? A small review would be nice.

I have it. It's a very promising packing, but...

1. The object files are incompatible with the ones used by everybody else (i.e. different from the developer's kit and from OSS Pascal). They provide a utility to convert developer's format to their own but not the other way around. Thus, I can't use MWC to write Pascal-callable utilities.

2. The MW argument passing conventions also seem to be subtly differnt from the standard. I wrote an OSS Pascal program that takes command line arguments and tried to call it from "msh", the micro C-shell that comes with the MW package. No go; the arguments never made it through. However, it works fine called as a .TTP file or from the PD COMMAND2 shell. Going the other way around, I recently got Beckemeyer's Multi-Tasking C-Shell and tried to call the micro emacs editor that came with MW. Also no go. It started up okay but it couldn't find its command line arguments.

3. The symbolic debugger that comes with the package is very nice and seems to work with MWC programs. However, I tried it with a random .PRG file and it refused to load it. I of course didn't expect symbols from such a file, but I did expect to be able to use the disassembler.

4. There are a number of annoying little bugs in the micro C-Shell that are
    not worth going into here and hopefully will be fixed in future releases.

In summary: If MWC will be your ONLY software construction package, the
I recommend it. The book that comes with it is nicely put together and
seems pretty complete and accurate. However, the gratuitous incompatabilities
with the rest of the world make it much less useful in a mixed environment
that it ought to be.

    Do they provide a resource construction set?

No.

I have got a 1040ST, but I have some questions about it.

1. I got the ST, actually called '1040STF' and I don't have the RF Modulator.
Is there any third party making a Modulator for ST ?
2. Months ago, I read from netland and know there is a CPM emulator availiable.
But, when I phoned to a Mail Order company, they told me that it is not out yet.
Does anyone here know where I can buy one?
I just heard from one of the guy in Compusereve Atari16 Forum that it is
put by Atari as public domain. Is that true?
I remembered that I once read a software list by Analog that the Emulator
is from Softronics.
3. I want to get some of PD disks for my ST, especially the HACK. Since I did
not save the messages, I did not have the address of people who offer

copying ST PD programs for someone like me. I am very appreicated if
 can share the PD disks with me. Please send me your mail address, format
of disk I need, also the postage I need to inlcude (I cannot get the US stamps
in Canada). Is there a PD disks pacakage called 'ST Starter Kit'? Whats are the
programs inside?
4. There is a game called ROUGE from EPYX. Has anybody here known that
if I can run it on a monochrome monitor?
5. Anybody here knows a National Wide Atari ST User group which has some
kind of newsletter and welcome the foreign users?

Thanks a lot.

RE:we've been experiencing some VERY nasty weather
here, (thunderstorms) BUT

Although you are using a plug strip ('power bar'),most of these units only switch AC hot and not the neutral line. Lightning strikes can jump the gap in those switches anyway. My suggestion, after you get your machine fixed of course, is to install a different switch so both sides of the AC line are switched and to add transient/surge protection.You can buy plug strips with the transient/surge protection built-in(expensive) or you can add MOV's(metal oxide Varistors-available at Radio Shack) to your existing plug strip. If you add it yourself put one between AC hot and ground;another between AC neutral and ground;and a third between AC hot and AC neutral. MOV's act like a gate and turn on to voltages over their rating (the ones at Radio Shack have a rating of about 130 volts),so they tend to regulate the AC line to somewhat 'normal' conditions and will conduct those nasty high voltage spikes to ground. But non of this is any good if you don't have a good ground at your outlet. If you live in an older home with 2 wire outlets make sure that the plug strip is getting the ground you need. You can buy cheap testers for correct wiring/grounding for $2-$5.

good luck,
John

>A program in ROM will have bugs left in longer (or forever)...
Writes Moshe Braner.

Well, if OSS is the same distributor for Action! this will not be a problem.
There were no less than 6 different versions of Action! within a years time.
All bugs were documented, and fixes were included in a newsletter, or available
on the Action! BBS run by Clint Parker. The support from OSS is nothing short
of wonderful, and any product which they can come out with would not have bugs
left in for a very long time.

The thing that made Action! so great was the environment which was created. I
would have to say that using Megamax in a 640K ramdisk has the same feel as
Action!, except that Action! code was cleaner. Still, Action! could be
produced effectively with a 128K (?) bank switched cartridge... :-)

In article <1095@batcomputer.TN.CORNELL.EDU> braner@batcomputer.UUCP
(braner) writes:

>Then of course, if a certain language is your DAILY working environment
>you would like it in ROM. How about an OPTION of getting it on a cartridge,
>in addition to the disk version, which is more appropriate for other buyers?

Well, TDI Modula-2/ST is my DAILY working environment. Including the
compiler, linker, editor, debugger, etc., etc., it adds up to about 800K (of
which about 500K lives on a ramdisk). Any ideas how I fit that onto a 128K
cartridge?

In any case, what do I do when TDI comes out with an upgrade? Throw away
my cartridge? Have a disk with ram patches?

The TOS experience should have demonstrated that getting a frozen program
to live in rom is non-trivial. (Apple did it, and then they realised that
the Mac file system was stupid: so they had to come out with a new operating
system with a file system in ram, and then a new machine with new roms.)

Re co-processors: that would seem to be reasonable, but I still want the
TT box which plugs into the DMA port. The 68000 doesn't coexist well with
co-processors (unlike the 68020), and, although you can do it, the effort
might not be justified.

In case you don't know, or haven't used Red Ryder much, it says that you can
use Red Ryder for 30 days, then decide if you wish to use the software, in
which case you are asked to send money for documentation and registration.
Otherwise, he asks that you destroy it, or pass it on to someone else.

It would seem to me that, Data Pacific is doing him a favor by providing a larger distribution base. It would also seem that they are not *ripping him off* as I have inferred from your message. They seem to be doing what any other person might do, passing on the software (among other software which was not mentioned by name).

Flame on

It seems that you are looking to start something where nothing is. If you truly care about Mr. Red Ryder losing his fair share, then take your grievance to him. Not by posting an insuating letter on the net.
I am not affiliated with Data Pacific or David Small, but I do not appreciate someone who is looking for an argument. Both companies are doing the ST community a favor.

Flame off

Keywords: MT C-Shell multi-user
Summary: Turn off the serial port

In article <5803@ut-sally.UUCP> joe@ut-sally.UUCP (Joe Hitchens) writes:
>A friend of mine who has the Micro C-Shell program is having difficulty
>getting it to operate in the 2(multi) user mode.
>He altered the /etc/passwd file and that allowed him to log-on, but
>immediately after logging on, it brought him back to the login: prompt.
>He is definately getting logged on under the new account name, but for some
>reason the shell prompt never appears.

  First comment - this is the multi-tasking "MT C-Shell", not the Micro

C-Shell, and it's not a bad package. I like what it seems to be capable of, but my hardware is a little too skimpy right now to run it properly.

I have a 520 ST with *no* extra memory - this is the biggest problem. (I also have only one double-sided drive.) The MT C-Shell kernal will try to get logins from the serial (modem) port as well as the console keyboard. Without a full megabyte, it will be unable to do so properly, so you have to change the file "\etc\ttys" to tell it to disable the serial port. Before I did this, I had the same thing, except that my modem was on and the transmit and receive data lights were flashing very steadily as the modem echoed the "login:" back to the Atari and the MT C-Shell would try to log in a user with that ID. I think you change "17tta0" to "07tta0" to disable it (BTW, the "7" means 1200 baud, and the "tta0" is the tty port name.) Once this is done, you should be able to log in as root or as any user you set up in the passwd file.

This is interesting on my system, but to be really useful, I'll need a hard disk. Anybody have a 30 Meg Supra and like it? Any comparisons with the Supra 20 or the Atari 20?

In-Reply-To: XBR4D76H%DDATHD21.BITNET@WISCVM.WISC.EDU, Mon, 22 Sep 86 16:08:31
+0200 (Central

    From Konrad Hahn:
    A quick view onto the partition information block (sector 0 of hard disk)
    showed that HDX created two overlapping partitions.
    Trying different partition sizes I found that HDX was only able to create
```

correct partitions if I selected one of the predefined partitioning schemes of the menu.
Did someone have similar problems with HDX ?

I most certainly did. I was using a non-standard sized middle partition (only 2 MB), and after loading on lots of files and folders to the first and third partitions, the middle one became trashed. However, John Fagins of Atari thinks the trashed middle partition was due to my exceeding the overall limit of 40 folders rather than to a problem with HDX.

I would like to look at the partition information I am currently running with to see if I currently have overlapping partitions. (I repartitioned into an 8-4-8 configuration (still non-standard) in the hopes that whatever caused the earlier problems would go away.) However, I don't know how to read the partition information block on the hard disk. I believe rwabs on sector 0 will give me the boot sector for the partition instead of the partition information block, and I don't know of any hard disk analogs to the BIOS floprd/flopwr calls for the floppies. How did you inspect the partition information block?

Magic Sac itself doesn't include any Apple code. Rather, you must buy a set of ROMs from Apple yourself.

Although not yet tested in court, there is precedence in the assumption that Apple cannot restrict sales of the ROMs to people who don't own MacIntoshes, stemming from the observation that mainframe vendors are required to sell their software to customers of plug

compatable machines. (We run MVS and VM on our Amdahls, for example.)

     The same assumption is being applied to the system and finder images which are also required to make Magic Sac work. I bought my system and finder from a licensed Apple developer. His license with Apple allows him to include system and finder images in the software he sells, and (he claims, I haven't read it) does not restrict him to sales only to Apple owners.

     However, Apple will not allow Data Pacific to resell the ROMs, or license Data Pacific for the system and finder images. This is also in accordance with precedence. (We get our MVS from IBM not Amdahl.)

     There are three separate legal issues in the Magic Sac, all of which Data Pacific believes they have correctly handled. The first two are the ROMS and system images mentioned above.

     The third is if Magic itself violates any Apple copyrights or patents. Since Magic is only a translator which intercepts some of the behavior of the Macintosh software and makes it work on the Atari hardware, rather than an emulator, it looks to me as if it doesn't violate any copyrights, etc.

Marty

     I didn't ask, assuming I was paying the $40 to them for their work, and would have to pay seperately for Red Ryder if I was going to keep it.

I have always made the assumption when given a diskette with shareware not written by the distributor on it that whatever I paid the distributor was for the diskette, and that I was still honor bound to pay for whatever shareware I use.

In the case of these diskettes, I assumed I was paying for the System and Finder images, and the cost of getting four diskettes.

(I'll probably keep Red Ryder and pay for it, since I use it on my Mac at work, and it seems reasonable.)

> Ah yes another volley in the "Well this stuff is OK but look at what we will
> have next year!" contest. Anyone for starting a "Best Announced but not
> yet available product" award?

Well, we ordered the several Floating Point Accelerators from Sun back in August 1985 (as soon as they were announced). We still haven't seen them, nor heard a ship date.

I've heard that they were shipping 5 or 6 times now.

We have seen great benchmark results from Sun though....

I vote for the sun FPA, it looks great on paper. (The GKS product is
also unobtainable, despite being in the catalog for about a year. However,
it is no where near as impressive as the FPA.)

I talked to someone who actually had his hands on one, so they may
be really shipping them now. He may have had a beta test version though.
I wouldn't call them available until you can actually get one without
waiting a year. (Hmm. A year is about what you are complaining about with
Motorola)

---rick

P.S Aside from the FPA and GKS vaporware, we are happy Sun customers.

(Although I wish they would quit gratuitiously changing the way programs
worked. My latest example is that repquota no longer prints disk usage
for people without quotas UNLESS you specify a flag. It would have been
backwards compatible to have a flag to supress printing disk usage
for people with no quotas. Oh well, it only took me an hour to
figure out way the quota system "wasn't working" anymore. I hate surprises.)

     Borland is rumored to be doing a Turbo port to the ST, but no one
seems to know when (:-)

     Metacomco (The Lattice C people) have a Pascal, for around $150,
but I haven't used it.

     OSS has Personal Pascal for around $70. It is a reasonable

compiler with a mostly complete ISO implementation, and full access to
ST hardware and software features. I use it a lot on my 1040, and am
reasonably happy with it. There is a relitively good manual which
explains the GEM library which is provided, although it is short on
examples. OSS also maintains a buletin board with examples and
tutorials.

     I don't know of any other Pascals off hand.

~~~~~~~~~~~~~~~~~~\ lineater, \~~~~~~~~~~~~~~~~~~~~

i know that this has been answered before but at the time i did not
have a 5 1/4" drive on my ST and i passed the postings by, so please
email answers to me to save net resources. anywho, 2 questions; 1)
can the atari read quad density disks (1.2Mbyte formatted) and 2)
where do you have to format the disks? on the IBM or the ST; does
anyone know why disks formatted on the atari cant be read on the
IBM, as in what is missing and/or needs to be changed in the ST
format program etc.

It seems I implied something that isn't true.

I bought the diskette set from Alex Leavens, who was also working out of the Data Pacific Booth. He is not working for Data Pacific, and I did NOT buy the diskettes from Data Pacific.

As I have mentioned before, Apple will not license Data Pacific to distribute the System and Finder images with Magic Sac, so I had to go to a licensed developer to obtain them.

What I received was four diskettes. The first contains the system and finder images. The second contains FreeTerm and Red Ryder. The third and fourth are Boston Macintosh User's Group diskettes in Magic format, although I don't have the distribution numbers handy.

I did not see this as an attempt to cheat any of the authors involved, and the only reason I can't give you a better answer about what the forty bucks was for is that I didn't ask at the show.

I know that I would be pleased to see my shareware distributed by Data Pacific if I were doing Apple Software. I find putting shareware on these disks to be equivalent to making it available through buletin boards.

I've had the Antic A-SEKA 68K assembler for a couple of days and I would like to strongly discourage anyone from buying it. The program is expensive (~35.00) for an assembler, and it seems like "standalone" .tos or .prg programs cannot be written with it.

First off the user interface is non-GEM. The editor is a line editor (YUK) but a regular editor can be used instead (I've used the OSS Pascal editor with the assembler successfully).

The most serious problem that I've had with this product is that although assembled programs seem to run from the debugger, it seems that they cannot be saved as .tos or .prg programs and run by themselves. I suspect that the programs produced by the assembler lack the information required by the OS to load and run them correctly. I had this problem with one of the example programs in the documentation - it ran from the debugger but not on its own.

The documentation is on the disk and one must print it on one's own printer. The documentation seems to be fairly complete (~30 pages) but there are almost no examples of programs to type in and run (I think that there are only two or three VERY small example programs).

When syntax errors are discovered in one's source code the assembler writes out an error message and then starts writing all sorts of mysterious characters to the screen for several lines...

On the positive side, the assembler seems to run very fast because all files are memory resident. The program is small enough (~17K) to fit on a RAM disk along with a reasonable editor (that you will have to supply yourself). The assembler has rather primative support for macros.

In summary this assembler seems to be useless since it appears that standalone programs cannot be produced with it (this may be due to my own inexperience -

but I couldn't even get the examples to run by themselves).

The program is not copy protected.

This program is the last program that I'll ever buy without getting a recommendation,
reading a review, or running it in the store first!

Perhaps those of you that are pleased with your assemblers can recommend one.
I AM ESPECIALLY INTERESTED IN GETTING AN ASSEMBLER THAT CAN PRODUCE CODE THAT CAN LINK TO OSS PERSONAL PASCAL!

Hope this helps,

Eric Bergman-Terrell

I have 1st Word version 1.03. I'm going to send away for the current version 1.06.

I'd really like to be able to print out the Hebrew, Greek, and other special letters in the font table. I have a Panasonic 1091 which is an Epson LX80 clone.

Some characters print ok (e.g. e with a "/" accent on top). Other characters cause the printer to overstrike incorrectly (e.g. a with a "/" accent on top).

If anyone could help with this, I'd be eternally gratefull!
grateful!

>>The bus data transfer rate of the 68030 is 40 Mbytes/sec.
>
>Think about this. That's a memory access time of 25 nanoseconds, more than
>4 times as fast as the memory we use in our PC's, Macs, Amigas, and Apples.

    100ns access time @ 40 Mbytes/sec (remember: 32 bit data bus). I think that the quickest transfer is 64 Mbytes/sec, which would come out to about 62ns access time. This means that your rams actually have to be a bit faster when you take into account bus buffering. It isn't unreasonable, and I think you'd be able to (finally) take advantage of dynamic-ram's block-read ability.

    I especially like the fact that they do MMU address translation in parallel with checking the cache. Anybody know what kind of page-table cache the MMU has?

Summary: It's up and running!

[]

After a period of planning and experimentation, we have the National Semiconductors 32081 floating-point math coprocessor talking to the ST!

("We", since I have collaborated on this with Andreas Andreou at Hopkins.)

Interested parties please e-mail to <braner@amvax.tn.cornell.edu.ARPA>, or at the address above, or call 607-272-3487, or write me at the address below. If the response is good, we might post some details. (If it is VERY good, we'll keep it a trade secret :-).

We have the 32081 connected to the cartridge port. To do that, the port needed some modifications. We suggest this mod as a "standard", since it is useful for many other purposes and designed to be easy to do and to keep the port usable for ROM cartridges and such too. Here is the mod:

Cut pins 1, 39 and 40 behind the connector. (No trace-cutting needed.)
Connect the CPU R/!W line to pin 1.
Connect the CPU clock to pin 40.
Build an address decoder that senses the address $3xxxxx (x=don't care) and is strobed by the CPU !AS signal. The best way to build this decoder is with one chip, a 74HCT138. The "HCT" stands for high-speed, LSTTL-compatible CMOS. Connect the decoded address strobe line to pin 39.

Since these pins are just redundant Vcc and ground lines, standard cartridge port devices can still be used, provided these lines are cut inside each device (which will then still work on standard ST's).

BTW, if Atari didn't bother to write-protect the ROM area, the decoder wouldn't be neccessary. This scheme will work with 2-Meg ST's too, but not with 4-Meg models, since $3xxxxx is within the fourth Meg. Addresses above $3FFFFF yield a bus error!

Summary: easy, both H & V, on the mono monitor

[]

After my warranty expired I opened my monochrome monitor (SM124)
and found LABELED adjustment points for BOTH vertical and horizontal
size. I managed to enlarge the picture considerably without noticable
distortion: the margins are now only about 1/2 inch around. Make
sure you use plastic tools for adjustment, and don't touch any high-
voltage wires!!!

Wrt to your BBS project for the ST:

The commands for retrieving and manipulating messages on every micro BBS I have ever seen have been hopelessly primitive. With a megabyte of RAM to work with, why shouldn't one be able to scan or read collections of messages by any combination of criteria of sender, receiver, time, text string, etc.? (For example: >Read From Jones To Smith During 1985 Text Qlisp) Why shouldn't an ST BBS (particularly on the forthcoming multimeg machines) be at least as sophisticated as Mark Crispin's MM mail processing program that is popular on the Arpanet, and perhaps, going one step further, include a small-scale natural language interface similar to Q&A?

Better yet, I would like to see a full-scale communications program for the ST that included all the standard BBS functions and the mail processing abilities of MM, Babyl, and Zmail (the last is standard on Symbolics machines, and is the most powerful mail processor I've yet encountered). Such a program would be quite intelligent about automatically downloading and storing the message bases of Compuserve, Delphi, Arpanet hosts, TBBS systems, Fido systems, etc., presenting a unified interface for offline retrieval, reading, and reply-writing, and automatically uploading replies to the appropriate hosts.

I don't actually expect you'll have the time to write such a program for your dissertation, but I wish someone at one of the major software houses would get on the ball.

Yeah...the binary would be great. I have MCC PASCAL at home, and I tried
compiling the source...one problem: there were some routines mentioned
in SPELL.PAS that I never heard of...one apparently was a modification of
some sort to an alert box. The function was, I beleive, called AT_ALERT.
What was that?

Actually, the list price is $99.95. (and, of course, you can get it for
cheaper from a mail order house...) It was the first high level language
that I got for the ST, and I quite like it. 32 bit integers, full
AES/VDI interface, etc. It comes with a decent full screen editor, and
a decent programming shell called MENU+. The only problem that I have
with the PASCAL is that it sticks a little *too* closely to the ANSI
standard...it doesn't allow for random access files. However, I also
have a copy of the Metecompco Assembler...so I remedied that problem.

Do I still use the PASCAL? Occassionally...but since I got Lattice
C, I use that for most of my work...

...ok...ok...so I like to stay with one company...;-)

Methinks you ought to RTFM...

```
         ev_breturn = evnt_button(ev_bclicks, ev_bmask,
                    ev_bstate, &ev_bmx, &ev_bmy,
                    &ev_button, &ev_bkstate);
```

```
     where ev_bmask: the mouse buttons to be taken into account
               when reading the mouse:
               01 = left button
               02 = right button
               03 = both buttons

I've tried it, it works...I think you should consider point (B) from
the second poster...

Caveat: I do not own an ST and have not seen any of the documentation
that is provided with it.

First the dma port ... can someone tell me what the pin assignments
are and the associated protocol ?

Cartridge port ... can this be written by the 68000 or just read? Are
```

the right lines provided so that an active device can read and write
main memory from the port?

Can someone suggest a fairly reliable document (cheap) that can answer
questions like the above.

I know this may be old but...

I need help wiring a standard RGB monitor to my ST. When all the
info passed thru the net regarding RGB problems, I was still
waiting for my ST. I now have it, and have consructed a little box
with a switch on it to select mono or colour. As I should have
guessed from the flurry of comments 9 months ago about RGB, I
should have anticipated a few more problems. Basically everything
works well, my little box turns the mono on/off and provides
composite video and audio.

The problem: the RGB output levels are analog 1 volt p-p. It seems
that standard RGB monitors (mine included) require
ttl level signals.

My attempted solution: I have tried breadboarding up an op-amp
circuit to convert the voltage levels to 0-5volts. I
am now able to get blurry images on the RGB monitor.

My request: - any circuit that will solve the problem.

- a definition of what exactly is 'TTL level' inputs
  for an RGB monitor (obviously the brightness is in
  analog form, which is not TTL (= ON/OFF)).
- any other comments or ideas.

I am kind of enjoying solving the problem but it is a little awkward
when I don't really know what my goal is, other than a good picture.

Thanks a whole bunch,
     Warren Long

Subject: LINK68 doesn't take path names .. Wasn't this fixed?
Message-Id: <1105@batcomputer.TN.CORNELL.EDU>
Sender: info-atari16-request@score.stanford.edu
To: info-atari16@score.stanford.edu

Hello,

I have the Developers C, and I'm having trouble with link68. I just
paid $20 for the new release of the C compiler, and I thought that the
"path names" bug was supposed to be fixed in it. Either it isn't, or
I'm doing something wrong. What I want to do is:

     link68 [options] x.68K=a:\lib\gemstart.o,x.o,a:\lib\gemlib...

This doesn't work. Am I doing something wrong, or wasn't it fixed?

I think someone posted a zap to the linker program to fix this bug.
I didn't grab it 'cause my check was in the mail, and I didn't think
I needed it. If link68 really is still busted, can someone please send
me that zap?

"..Oh, that's disgusting, isn't it?" - Brundlefly, The Fly
****
The linker reads backslashes as comment characters.

Looks like THAT bug didn't get fixed with this release...

Anyone interested in a WORDS.TXT file for Eric Terrell's
SPELL.PAS? Check first of all the SPELL utility (if
available) of your local host to see whether you can tear a
dictionary file out of it. For those who can't find such a
file I have a 42297 words dictionary for anyone who asks for
it.

I ran into exactly the same problem. The problem is caused by ':' being used
as the field seperator in \etc\passwd and also being used by gemdos path names.
What had happened in my case was that i specified my home directory
to be 'E:\bammi'. Now when i login, login reads \etc\passwd and find that my
home directory is 'E' (the ':' in the pathname terminated the passwd field),
which is not a valid path, so it refuses to let me log in. I have informed
David Beckemeyer of this bug. For now the solution is to tell passwd that
your home directory is \usr\foo on the drive on which MT c shell live. In
\usr\foo you put in a profile.sh that send you off to your real home, after
modifying the home variable appropriately.

About a week ago I posted a request for help with terminal lookup
connected to a Vax via Telenet. Since then I have received a number
of suggestions as to what to do. I have also discovered a workaround
but no real solution. The only way that I can connect up to the

specific remote that causes the problem is to

1. Dial Telenet with Xon/Xoff enabled (no other setting works).
2. Logon to the Vax with Xon/Xoff enabled.
3. Turn Xon/Xoff off and enable CTS/RTS as soon as the login is
   complete.

This is an Atari problem because the IBMPC at work and my Kaypro use
Xon/Xoff and connect with no problem to that Vax. Since the Avatex
does not have CTS connected, step one is necessary to get the modem to
dial, but I think CTS/RTS would work throughout the procedure if the
Avatex had the CTS line (funny why it doesn't balk when I change to
the CTS/RTS handshaking in the middle of things).

[]

According to Atari (in a memo they sent to dealers), the high-pitched
whine comes from the "inverter" chip, a little DIP on the mother-board
that converts +12V to -12V. It oscillates to do it, ==> whine. The
only (?) load on the -12V line is the RS232 port and related driver chip
(1488). So it is not surprising that whatever is plugged in there affects
the whine. Atari has also sent the dealers instructions on how to eliminate
the whine, which I posted here a while ago.

Summary: The 68030 is MUCH faster than that . . .

In article <2270@gitpyr.UUCP> Rodney Ricks writes:
>The chip is said to run software 20% to 30% faster than the 68020.

I believe I read a press release about the 68030 in which it was stated
that the 68030 was capable of 8 MIPS, approximately 8 times that of the
VAX 11/780, and 2 times that of the 80386. This is at a clock rate
of 16-20 Mhz, I'm not sure which. The 68020 is capable of about 1.5
MIPS at a clock rate of 14 Mhz. This puts the 68030 at about 5 times
faster than the 68020 at the same clock rate. Apparently the 68030
uses what is called "Harvard parallel architecture". Now that Motorola
has released this chip, they have in *every category of chip* a far
superior chip than does Intel. 68030 > 80386, 68020 > 80286, 68010 and
68000 >> 80186, 8086, 68008 > 8088. The 68000 series chips are in every case
more orthogonally designed, faster, more compatible with each other,
and easier to program.

It is unwise to send any text file as large as 64K bytes. Although many sites
can handle more some cannot, and silently truncate. That's the reason large
postings come in as "Part x of y". Best do it that way to be safe.

     I have the following (not verbatim, I've already filed the issue
in the circular file (:-) report on the 68030 from last week's EE-Times
magaizine:

     So many trade publications were writing about the 'impending'
announcement of the 68030 (and 68040) chips that Motorola decided they
had better announce the chip. They won't be shipping sample quantities
until next July.

     I don't remember details, except that it has a 32 bit wide data
and address path to memory and uses higher clock rates than the 68020.

Marty

Um....your 8-bit uP background is showing. If the 68030 is handling data
at 40 MBytes/sec, that's 100 nS per bus cycle time. The '030, like the
'020 is 32-bit machine -- it does 4-bytes at a time.

>>Now, when will I be able to connect one to my Amiga?

>1 MB DRAM with 25 ns access which will sell for less than $100 apiece :->

Well, 1M Drams are normally 100nS, so even with the "normal" chips, it
may get by with only a few wait-states. In any case, one of the reasons
that the '030 is supposed to be faster is that it has a built-in data-cache
in addition to the program-cache that the '020 has.

Yes, SEKA is absolute garbage. It is one of the *worst* assembler/
editor packages I've ever seen. (It floated into Atari about six
months ago, and I recall using the disk it came on as a blank one,
about an hour after I first tried to use it....)

Don't buy it.

    After a couple of moments of thought, i would say why not use the printer port. Think of the printer port as a parallel Input port with one interrupt input - the strobe. I would put the serial output of the tablet, through a Usart, to the parallel input port. The data ready strobe of the usart would drive the interrupt (strobe) input. The power for the usart can be tapped off the joystick port.
    Then all that is left to do is to write an interrupt routine to handle the strobes. There is interrupt reserved for centronics strobe, that is routed through the MFP and the 68000 see it at IPL6. So your sampling frequency is only limited by how fast you can process the interrupt. By putting the usart, you have effectively a 8 bit buffer, so the sampling rate requirement should go down quite a bit, as now you are going to sample 8 bits at a time. This should work pretty good with tablets like the Summargraphics, which i seem to recall, send out data as 2 4 bit packets in any case (at least that is true in one of the modes), which the usart will latch and pass on.
    I know its easier said than done, but its another idea off the top of my head. Hope it helps some.

It exists, mostly, on paper. All of the details have not yet been decided,
so it isn't even vaporware yet -- it exists only as an announcement by
Motorola to try and keep designers from designing in the 80386 until they
can (quick! hurry!) get something better on the market.

Intel didn't announce the 80386 until they had it (mostly) working, in
real silicon. Motorola should be ashamed.

Probably the most significant feature of the 68030 is that the MMU is
on-chip. This is a big win in terms of speed/cost. It also has a data
cache in addition to the code cache. I think there are probably other
little tweaks for more speed.

Maybe Atari should just wait until the 68030 comes out to replace the
ST. :-) On chip MMU means lower cost/simpler board, and should have
fewer wait-states with regular DRAMs.

With microprocessors that are this fast, it starts to make sense to use
Lisp for program development and to forget about "lower-level"
languages like Pascal, C, Ada... :-)

A next generation ST could have a small Lisp interpreter (like XLisp)
in ROM. Lisp compilers are getting quite good. The ORBIT compiler
(for Scheme) generates code that compares favorably with compilers for

more conventional languages (see "ORBIT: An Optimizing Compiler for Scheme" in the "Proceedings of the SIGPLAN '86 Symposium on Compiler Construction", SIGPLAN Notices v21, #7). There are comparible compilers for PSL and Franz Lisp (and possibly others).

I would hate to be accused of being the originator of rumors concerning the financial health (presumably, ill) of Atari. In retrospect, the question in my mind about Atari's finances, generated by a cable TV program that I now believe was over 2 years old, should have remained where it began: in my mind, and NOT on this net. I could, and should, have brought up this question via a medium that does not get such wide dissemination. I am now confident that the cable TV show was discussing the state of affairs of Atari in pre-Tramiel, pre-ST days when they were still owned by Warner Communications (and, AT THAT TIME, in BIG financial trouble). End of rumor.

New rumor: who is porting NASTRAN to the ST?

If the 68030 is anything like the 68020, you probably only need 100ns
cycle time memories, since the bus can be four bytes wide. The access time
will have to be less, though, to allow for setting up the address.

I think it should be possible to build a small, fast, cheap machine using
the 68030 at nearly full speed. The trick would be to not use cache memory,
just make it all fast. You only need 16 8KX8 static RAM's to make up 128K
of memory. So a *really* fast 128K Mac ought to be possible.

The question is, does anyone want one? Or would they rather have 2M of
slower memory for the same price?

>and easier to program.

I agree that the Motorola chips are nicer in many ways than the Intel chips.
But to say Motorola has "released" the chip is stretching things a bit. Not
only has the 68030 not been formally introduced as a product yet, but the
artciles I've read (e.g., Electronics, September 18, 1986) say volume
production is more than a year away. The 80386 is here now, and actually
has a system available (Compaq) which uses it. In other words, it's not

really fair to compare that which Intel has now with what Motorola will have
in a year. A more fair comparison is between the 68020 and the 80386.

.

According to postings earlier this summer Beckemeyer Dev. was to have
released their SCSI interface and clock board in mid August. Does anyone
know if they have done so? oe btter yet, has anyone actually got one and
have anything to say about it?

[]

The TT will be a UNIX machine and cost several $K (?).
It is NOT an add-on to the ST - it's just the opposite!

The 32081 chip, 6 MHz version, quantity one, costs <$30.
A working board with it could probably sell commercially
for about $200.

If all you want is fast FP, what would you get?

INTEL AND MOTOROLA JOSTLE FOR DESIGN WINS

Intel and Motorola continue to vie for position in the 32-bit MPU league. Motorola is expected to introduce its 68030 sometime next month, while Intel will see its 80386 moving further into the artificial intelligence market as software suppliers come out in its support at the AAAI symposium opening in Philadelphia today. According to reports from the US, the 68030 tweaks the architecture of the 68020 for increased performance. It is the forerunner to the 68040, Motorola's first 32-bit processor with on board memory management unit. Details of Intel's 80486 are still sparse, but the direction of the 80386 into the AI market suggests that the new part will be optimised for AI applications in knowledge-based systems and natural language interfaces. Key goals for the 80486 are the support of Lisp and Prolog, with all products targetted to support Unix System V. Among the companies reported by US trade paper, Electronic News, to be working on AI languages and development environments are Gold Hill, which will have a System V version of the GCLisp 386 developer with compiler, interpreter and Emacs editor by the first quarter of 1987; and Lucid, with its Common Lisp environment with compiler, interpreter, debugger and foreign function interface. Franz will have its Common Lisp environment and tools ready in the autumn; while Arity is planning a Prolog programming environment plus tool set for early 1987. Companies still expected to make a formal commitment of support are Quintus and Teknowledge.

The way you want to do this is correct. Although it is not easy, you can change the x and y coordinates of the parent object (usually a g-box, probably in this case an invisible box with no border) which would change the relative position of the children on the screen, though they would be positioned the same relative to the parent.

If you can, look at Tim Oren's tutorials on GEM, and the DRI Doodle program, both of these will give you an idea of how to manipulate the x and y coords of an object. The particular algorithm you use, however, must come from your own power.

Mike

Two more comments:

1. Saving to disk is incredibly slow with microemacs 3.7 (I experience "long" waits even saving to a ramdisk)

2. The black border is a nuisance.

Any chance we may be given the sources to correct these problems?

Apple only allows the ROMs to be sold through authorized apple service centers.

There is a fascinating grey area in the law regarding the restrictions Apple may or may not place on who the service center can sell them to, and if the purchaser can then resell. . .

The ROMs were being sold at the B&C computer visions (A Santa Clara Atari only store) booth.

Do not despair! The new version of UniTerm will be posted to the whole net
in a few days (it even survives VTTEST quite well now).

Robert Royar writes in one of his postings:
> ...I have been experiencing problems with my terminal locking up on one
> of these VAXES....

Does anybody have an idea why this happens? It is not the terminal program
in my opinion, but the MfP or the bios getting hanged up, is there any fix?
ST-Talk probaly installs it's own interrupt handler.

Hmmm... $40 is the price for Red Ryder. Does that mean that they are

paying for Red Ryder for you, or is the $40 you payed Alex Leavens in
addition to the $40 that Scott Watson should get for Red Ryder?

If the $40 to Alex Leavens does not go to Scott Watson, do they make
it clear that you haven't bought RR?

Hello Phil,

Thanks for answering my message. I couldn't send this message directly to
you (lll-lcc!eckert@cad). I couldn't kill the adventurer to give his body to
the dragon (no weapons). I don't think the dragon wants a dead body because
I killed the princess and gave the body to the dragon and he killed me anyway.
The hint said something about illuminating but I wasn't successful.
     By the way, I have gone down the lava river and seen a drunk man.
                            Duy

The reason you'd want to partition your hard disk is that GEMDOS
has problems with a disk size larger than I-forget-what. Perhaps
if Landon Dyer is reading this, he could give more exact details.

> uuencode.)

Uuencode is assuming that you know about standard input and output.
Since you used standard output redirection, (the > sign), it sounds
like a reasonable assumption. This lets you pipe things to uuencode,
for example.

> To uuencode into a local file, I found the following syntax to be necessary
> (or at any rate sufficient, which is sufficient!):
>
>   uuencode inputfilename anystring >output filename

You could also use:

     uuencode anystring <input >output

I agree that uuencode's command line leaves something to be desired.
It would've been better to make the "destination string" be an option
(eg uuencode -d deststring input >output). I just thought I'd remind
people that "programs that default to reading from the keyboard" are
really "programs that default to reading standard input" -- a good thing.

I thank George for pointing this out. Actually I suspect that *all* system
administrators have a low tolerance for inappropriate or excessive mail
going through their systems -- they just don't notice as much as we do.
One window on my Sun screen constantly displays the modem/uucp/mail/news
activity going on, so when I'm working I notice who is sending what through,

and I take the time to educate people who are wasting resources. Letting
everybody know what works and what costs what is vital to keeping this
wonderful shared network without accounting or fees going.

     John

the new version (3.7i) will support 3 resolutions: low and med for
color-corresponding to 25x40 and 25x80; and med and hi for b/w-
corresponding to 25x80 and 40x80
source will go back to Dan Lawrence to be included into the production
version of MicroEmacs for future releases, please send him or me any
changes that you make so that we can have a single ST port for sanity

Summary: Right on!

[]

I sure agree with John: memory is being squandered uselessly!
That 4K screen-editor for the Apple II I mentioned is rather complete
(no multiple windows, though). I read about a utility for Apple Pascal
(on the Apple II) that reminds one of Sidekick in what it does. It eats
all of about 5K - Sidekick gobbles between 26 and over 100K, depends on
what parts of it are installed. Why? because it was written for a 640K
machine, sloppily. People will tell me that we will want "real" EMACS
and graphic-UNIX on our personal machines when they finally have 2
Megabytes (4 ?). What for? Use the RAM (even part of the 1 Meg space
we have now) for an intelligent, transparent disk caching scheme at
the OS level, and (with one floppy) it will put hard disks to shame!
Instead of silly BASIC environments with 17 windows (edit in one, list
in another, etc.) - let us have an incrementally compiled BASIC (or C,
or Pascal)! An incrementally-compiling environment needs RAM for many
things: source, executable code, variables (that remain intact while
you modify source and continue running!), compiler, editor/lister/decompiler
(or whatever that is), library routines, and (yes) a graphics screen.
THAT'S what RAM is for! (HBASIC actually compiles at edit time and
DECOMPILES at list/re-edit time. So fast, though, that you don't notice.
At run time, it RUNS! 2000 times faster than BASICA (sieve benchmark)!
THAT'S what a 16/32 bit processor is for!   Did you hear of the brand-name
"supermini" that serves many users simultaneously with a famous OS,
but performs floating point operations a lot slower than Applesoft BASIC?
(That's a true story, but the company that made it is so big I'd rather
not mention them by name :-)

- Moshe Braner

Peter's principle of computer engineering:
     Software will expand to fill the memory allotted.

[]

For a long time I wanted to create a very simple, easy-to-use system
for plotting functions, data, etc from a C program. I am thinking of
scientific/engineering applications, where quick, one-shot plots are
wanted, not fancy, perfect, art pieces.

Well, I did it after all - it wasn't as hard as I thought, since I have
already done it before in Applesoft BASIC. Happy plotting!

Keywords: Unix Shell
```

A friend of mine who has the Micro C-Shell program is having difficulty
getting it to operate in the 2(multi) user mode.
He altered the /etc/passwd file and that allowed him to log-on, but
immediately after logging on, it brought him back to the login: prompt.
He is definately getting logged on under the new account name, but for some
reason the shell prompt never appears.

It would go something like this:

Login: john
Password:

Welcome to the Micro C-shell Multi tasking .. etc...

Last Login Monday September etc ...

Login:

And that's it. It just goes back to Login: and does the same thing with
all user names.
Does anyone out there have any ideas why this is not working? Has anyone
else had a similar experience with this piece of software?
Thanks in advance.
j.h.

Re: O/S Updates

It is not putting the O/S in ROM that frees up memory space.

It is putting the O/S up at the top of the address space that frees up

RAM space.

Why not use one of the CMOS battery backed up memory chips that is pin for pin compatible with standard ROM (not sure if it's the RIGHT ROM tho) in an ST and load it with the ROM version of TOS? Or any other desired O/S? If you wanna be fancy it could go on a piggyback board, much like the RAMrod board for the 8-bit Atari 800XL, and let you switch the RAM section to

(1) act like RAM just below the normal ROM (or wherever you feel like putting it)

or

(2) replace the standard O/S ROM.

Then you could load it under the control of standard software and then with one magic write to a control address it would replace the standard ROM. With this arrangement it wouldn't even need battery backup unless you wanted to remove the standard ROM for some reason.

(BTW, no news on Mumps? My-mail: Tue 2 Sep 86 08:22:52-PDT
Subject: MicroMumps for the ST?)

I -Digitizers for the ST?-

As many may have noticed, a mouse is a very handy instrument for walking through menus, creating rectangular boxes etc. For entering subtle graphics it is awkward. Just try to enter your signature with a mouse (....). The difficulty is caused by the orientation sensitivity and scaling problems of the mouse and the fact that we use the fine musculature of the hand in

normal writing and drawing. Therefore we are searching a digitizer tablet for the ST in our project on handwriting recognition and -simulation.
A 1040 ST could become a graphics workstation, connected to a VAX via the serial interface.

II -Ports-

As I can think of, there are 3 possibilities:

(a) replacing the mouse by a tablet (this demands dedicated hardware).
(b) connecting a digitizer to the DMA interface (dedicated hardware).
(c) connecting a digitizer to an RS-232 interface (general solution).

Although we prefer solution (c), we want the workstation to be connected to the VAX all the time: so we would need a second RS-232 interface for the ST in that case.

III -Sampling-

Another problem we have is the tablet sampling frequency. This frequency should be adjustable from 100 Hz (min.) to 200 Hz or up. Also, the tablet should *not* have any intelligence since we want to make a time record of the displacements of the pen tip.

Any information on this subject (hardware/software) is welcome!
We would like to convince our officialdom that the word *ATARI*
is no Japanese for "Video Freak Toys Only".

Hi,

I know many people have put notes here on successful upgrades of the 520. If you have, or if you can make a recommendation, would you please drop me a note stating cost, vendor, and ***original state*** of your ST (ie., what model 520). Thanks for any comments.

The fact is that the AES event library calls do *not* allow you to wait for
a right mouse button event. In order to use the right mouse button, you
must poll the mouse. Methinks the gentleman has a valid gripe.

>Rodney Ricks

The Electronic Design article you reference contained a misprint. The 68030
is *not* 20-30% faster than the 68020, it *is* 50- 75% faster than the
68020 (at equivalent clock speeds). Also, the 68882 is *not* 25% faster
than the 68881, it *is* 100-300% faster (2x-4x).

In the Antic magazine for this month, there is an ad on the MS-DOS emulator.
This emulator is done via software and it costs $150. Does anyone know about
this product? How fast does it emulate? Comments are appreciated.

Summary: info on disk size limits

The ST hard disk format is that same as used on MS-DOS 2.X systems, and has its same limitations. In particular that's where 32MB size limit per disk partition comes from. The only way to make it bigger would be to increase the number of sectors per cluster, which may or may not work under GEMDOS. (And it would depend on whether or not the driver would understand logical sector numbers that didn't fit in a 16-bit word).

The code to create/delete files in GEMDOS is particularly slow (probably because of seeking back and forth between the FAT and where the data is being written much more than it should). This is the reason for the recommendation that partitions have a maximum size of around 10MB.

I will post a uuencoded binary of my SPELL program as soon as I get 'phone service (should be Monday, September 29).

About the dictionary for SPELL: in the user's guide I mentioned that a dictionary file (really a list of words) is built by the program itself. The program starts out knowing no words, and asks about each word in the

file being corrected. After the program has been used for some time, most
of the words that you use will be known to the program, and it will only
ask about new words and misspelled words.

There is no problem with starting out with a big dictionary file. Just name
it words.txt and place it on the same disk with spell.prg. This file should
be an ordinary text file with one word per line.

I don't know where you would get such a file...

Hope this helps. I'll post the binary file as soon as possible.

Summary: new ST roms -> blitter upgrade

The rumors about a new set of ROMS for the ST might come from the work
being done on the blitter upgrade. As part of installing that upgrade,
a completely new set of ROMS must be inserted to support the blitter.

At the San Jose Atari show, where a couple of 1040's in the Atari booth
were running with the blitter, Sam Tramiel announced that the blitter
chip was done (though I'm not sure whether his announcement implied that
the roms to support the blitter were also complete). To upgrade existing
ST's, a version of the blitter is packaged as a 64-pin DIP. That package
is piggy-backed on top of the 68000.

Summary: megamax c update info

I talked with the Megamax people at the San Jose Atari show, and they stated
that an upgrade to version 1.1 was available (and in fact if I had had my
master disks with me they would have done the upgrade on the spot).

It was also stated that a future version (a couple of months away???) would
have at least an absolute code generation option, thus removing the 32KB
segment limit.

using TECO is a sick idea (:-)

seriously i don't think that you are power mad and all of your requests
are very reasonable just harder than blazes to implement, consider for
example that redirection of i/o (dup) doesn't work with code generated
by some compilers and does work with others, and to do most of what you
want (which again i feel is reasonable) you need MocLisp ......

give me a solution and i'll implement it

The Northern California Atari Expo this past weekend in San Jose had a few
interesting developments besides the first sales of the Magic Sac (aka Mac
Cartridge). Here's a brief report:
   About 5000 people attended during the two days of the show. Among the
speakers were Atari officials Sam Tramiel, Leonard Tramiel, Shiraz Shivji,
Sig Hartmann, Richard Frick, and evenmyself. Other speakers included
Jerry Pournelle, Tom Hudson, David Beckemeyer, Frank Cohen (of Regent),
and Paul Heckel (Zoomracks).
   Xanth displayed an amazing new ST animated demo, topping their previous
effort of Fujiboink. This one had 4 large "bubbles" moving in and out in an
"eggbeater" pattern. The lower part of the screen was the name Atari and
the Fuji logo, and above the top of the screen was a red-white checkerboard
pattern. Both the lower and upper areas were faithfully reflected on the
bubbles. Xanth also showed an ST version of _Mazewars_ which permitted up

to 15 ST's to be MIDIed together. For the uninitiated, this game is a 3-D 1st-person-perspective game where you wander around in a maze trying to kill the other players. The scrolling was very smooth. No word on a commercial release, and they seemto be leaning toward making it freeware.

Speaking of multi-ST games, the FTL folks had a very pretty dogfight game for 1 computer or for 2 players with 2 ST's and MIDI cables. The graphics were similar to the games from Microprose, and the play action was so good that it was almost impossible to get near the machines all weekend. FTL also showed a later version of the dungeon game demo available here on BIX. The graphics are truly outstanding here. Availability of both games is October.

Antic was showing their 3-D liquid-crystal-shutter glasses again, with some better demos than last time. Still no sign of Jez Sans' Starglider game adapted to the glasses, though. Also from Antic was the 2nd issue of STart magazine, a very good-looking issue and a great improvement over the first one.

Metacomco unveiled 3 new programming tools: Cambridge Lisp, an interpreter and compiler with good GEM support added; BCPL, a C-like language (near as I can tell); and a Make utility. All are available right away.

Regent Software had their Regent Word 2, an upgrade using the normal ST character set (which made jerryp very happy) and full GEM support. They also showed Regent Base.

Michtron had their videodisk controller ready for sale, along with an adventure game driver and the Dragons Lair disk. Since Dragon's Lair is old hat for arcades, it seems like the disks can be had for very little, so the folks at Michtron added a parser so the ST can control the action. Michtron also have their ST Pool game ready to ship, another very nice implementation.

QMI displayed a lot of vapor products that look quite nice. Steve Grimm's BBST is coming along nicely, including support for QMI's forthcoming ST-Net so multiple ST's can be linked to make a larger BBS. The big news from QMI was their Desk Cart, a cartridge-based desk accessory package similar to Cornerman but without all the memory being taken up. They also showed the ST-Talk Professional 2.0, ready to ship Real Soon Now.

Quickview Systems is almost ready to ship their Zoomracks 2, a GEM-based program which seems to have incorporated many user suggestions to make it easier to use and faster.

Haba was showing a few products that seemed a lot better than some of their earlier efforts. In particular, their Haba View data base manager which makes good use of the GEM user interface to create customized databases.

Hippopotamus was selling their ST Sound Digitizer and their Video Digitizer. The sound product was interesting -- more when I've had a chance to play with the one I took home.

Oh yes -- I'd better not forget to tell you what Atari showed. We had 2 ST's with the final working blitter chip. We were able to test this with a few programs, including a nearly final version of Degas Elite, and everything seems to work very well (not to mention much faster). The blitter really helps when large pieces of memory are being moved, since there's more overhead to set it up than the RAM blit but less time actually used in the movement. Looks like a 1st-of-the-year release for the blit upgrade, at about $120. Atari also had ST Star Raiders on display. This one's on sale now. A later version of Microsoft Write was shown, supporting features not seen at the LA Fair, specifically support of GDOS-based proportionally-spaced fonts. Going to be a _nice_ word processor, available late in the year.

(And I accused QMI of vapor???)_
   Supra had their 60-meg hard drive on sale for $1795 (show special, the regular price is $1995). They cooked up a special slide show demo that was really moving -- several feames a second, straight from the hard drive.
   There were several booths showing MIDI software and products. In facrt, one of the highlights of the show was having the ST on stage controlling _all_ the synthesizers at the show, even the ones in the booths on the floor! Talk about surround sound...
   Next stop, Portland OR, October 11-12.

I had no problems with the high-pitched whine described by some people until I plugged a generic null-modem onto the cable attached to my RS232 port. When I removed the null-modem, the whine would stop. It wasn't always there when the null-modem was attached. (I don't think the problem was related to the particular device attached to the other side of the null modem.)

The null modem passed pins 1 and 7 through, swapped 6 with 20, swapped 2 with 3, and tied 4 and 5 (same side) together and fed them to 8 (on the other side).
The null modem was symmetric (ie, it looked the same from both ends).
I'd guess the problem was because 4 and 5 were tied together.

I have since constructed my own null modem that did only the pin switching that I needed. It is connected to the same device as before. The whine is no longer around.

Moral: if you have the high pitched whine, unplug your RS232 cable (if any) and see if it stops.

By the way, I've had my 1040ST since March and have only powered it off about 4 times (mostly because of power failures). I've had no problems with overheating (room temp is usually 65-80 degrees F). I chose to try rarely power cycling my 1040 as a way of minimizing component failures. So far I have had no problems (but this is only one sample!). I do turn off my monitor when it is not in use.

I received Uniterm a few weeks ago but I couldn't get the documentation for it because I don't have access to proff. Would anyone please send me a copy of proff, either source code or executable code. Also, Uniterm works fine in vi except when the cursor is moved around (it deleted everything in its way). Can anyone send me another version of Uniterm.
    Thanks.

     Does anyone know what type of interface Atari or Supra uses to
convert the DMA port to a SCSI bus for their hard disk?

     I am particularly interested in what specific ICs are used in the
interface as I am in the process of connecting a Micropolis drive (fast!)

to the Atari ST. Any information is helpful and appreciated.

>So GNUEMACS is too massive for the ST... Is there a REALLY decent editor
>out there for the ST that an EMACS addict can live with?
>Micro-Emacs is nice and powerful, but it ain't EMACS. (Actually, the only
>real EMACS is the original one written in TECO. GNUEMACS is considered an
>EMACS-like editor.)

No, according to the GNU Emacs Manual by Richard M. Stallman, GNU
Emacs is the Unix/GNU incarnation of the advanced, self-documenting,
customizable, extensible real-time display editor Emacs. It is a "real"
Emacs, as opposed to nonextensible editors with Emacs-like command
bindings ("ersatz emacses"). At least, that is the distinction that
RMS makes, and he is the author of both GNU Emacs and the original (Teco)
Emacs.

>Any interest in implementing TECO on an ST? Is this a sick idea?
Yes, it is a sick idea. A TECO with enough stuff to run TECO Emacs,
even if such a thing is possible on an ST, would result in an Emacs
almost as big as GNU Emacs. Porting GNU Emacs is probably a reasonable
idea for a 2MB+ ST, as mentioned here before.

Hello,

I have the Developers C, and I'm having trouble with link68. I just
paid $20 for the new release of the C compiler, and I thought that the
"path names" bug was supposed to be fixed in it. Either it isn't, or
I'm doing something wrong. What I want to do is:

     link68 [options] x.68K=a:\lib\gemstart.o,x.o,a:\lib\gemlib...

This doesn't work. Am I doing something wrong, or wasn't it fixed?

I think someone posted a zap to the linker program to fix this bug.
I didn't grab it 'cause my check was in the mail, and I didn't think
I needed it. If link68 really is still busted, can someone please send
me that zap?

[]

Are there plans for a new batch of ROMS to fix that problem with 40
directories per session? I won't even consider buying a hard disk,
(no matter how much I'd like one), with a limitation like that.

Summary: It ain't goin' in PC's

In article <2270@gitpyr.UUCP> rodney@gitpyr.UUCP (RODNEY RICKS) writes:
>In the September 18, 1986 issue of Electronic Design magazine, there is an
>article on page 27 describing the new microprocessor from Motorola, the 68030.

>The chip is said to run software 20% to 30% faster than the 68020. The chip
>is supposed to be available in mid-1987, along with an improved math
>coprocessor, the 68882, which will be up to 25% faster than the 68881.
>

I hope the '82 is more like twice as fast as the 68881.

>The bus data transfer rate of the 68030 is 40 Mbytes/sec.

Think about this. That's a memory access time of 25 nanoseconds, more than
4 times as fast as the memory we use in our PC's, Macs, Amigas, and Apples.

>Now, when will I be able to connect one to my Amiga?

Probably soon. But it won't be noticably faster than a CSA 68020.
An editorial on the subject of the 68040 (yes, 40) in a recent issue of
a small PC magazine commented that these chips are so fast that a fair
amount of high-speed cache memory is absolutely essential to take full
advantage of them. And that means minicomputer pricing, not micros.
Unless one of you hot-shot chip designers out there can put together a
1 MB DRAM with 25 ns access which will sell for less than $100 apiece :->

              Stephen Walton, speaking for myself

Dudley Moore: You must be a nut case!
Peter Cook: They said that about Galileo! They said that about Einstein!
Moore: Yeah, well they've said it about a lot of nut cases, too.

1) Does anybody know whether (unmodified) micro-emacs in general, and the
   ST version just posted - supports the full international ascii set ?

(The version I have right now doesn't, which means that I can't write
big text at home (I'am using LATEX).

2) Is it true that the new ST version bumps out with a monochrome monitor ?

- thanks for a reply / Daniel

STEWART ALSOP'S P.C. LETTER
September 24, 1986

THE NEW ATARI CORP.: MAKING NEW MONEY AND NEW MACHINES

I love to see Atari proving everybody else wrong, not the least because I was crazy enough in my very first issue to say that I thought Atari would survive and prosper under Jack Tramiel's redoubtable leadership. Now the company has decided to offer its stock to the public in a bid to get out from under the clouds left by its unusual "purchase" of the assets (if you could even call them assets) of the Old Atari Corp. from Warner Communications. If it's successful in selling 4.5 million shares for about $12 a pop, the company will have enough money to pay off Warner, some of its creditors, and still have enough cash to add a few million to the $29 million or so it already has in the bank.

At a minimum, what Jack Tramiel and his sons have managed to do with the carcass of Atari is nothing short of amazing. When they acquired Atari's inventory and name, the company had a video-game machine and two computers that were costing about twice as much to build as they were selling for (if I read the prospectus correctly). The Tramiels have since reduced costs on the old Atari products so the company now pretty much breaks even on them. In the interim, the company redesigned the 2600 game system and 400 and 800XL computers

(now called the 65XE and 130XE) so that they could sell them profitably. And, in what amounts to a remarkably short time (about nine months), Atari has designed and delivered a completely new computer that, despite its low pricing, makes the company a ton of money on each unit. The net result is that Atari went from selling about $7 million worth of old, unprofitable products in the first half of 1985 to selling $89 million worth of new, highly profitable products in the first half of 1986.

Since shipping the 520ST in July 1985 and the 1040ST in about March of this year, Atari has managed to sell more than 150,000 ST computers worldwide. If I was to guess, I would say that about 60,000 of those computers have been sold in the U.S., about 25,000 in West Germany, and the other 75,000 in the rest of the world. That's not too shabby, particularly compared to Commodore's record of selling less than 100,000 Amigas in the last 12 months. But the widespread distribution of STs around the world makes the ST a tough market for software publishers: it's hard to even identify good distribution, much less promote products efficiently. But it's just enough to take the ST seriously as a viable format (particularly given Atari's always vague product plans, detailed below). Remember that everybody was writing off Tramiel's Commodore in 1982 and 1983 when it was selling most of its computers into Europe. It's reasonable to assume that, just as he did with Commodore, Tramiel will use his overseas sales to build up Atari so it's strong enough to take on U.S. mass merchants in earnest.

Atari hasn't been sitting still in the new-product area. The company introduced two and four megabyte versions of the ST at the recent PCW show in London: the 2080ST and 4160ST. From what I saw in Atari's labs yesterday, those computers haven't really been finished. But the company also plans a repackaging of the ST that it will introduce at Comdex, which is when you'll probably see the higher-memory versions of the ST. The new package will be a two-inch-high box with a built-in, 3.5-inch floppy drive, a built-in power supply (finally), a bracket for an internal, half-height hard disk, detached keyboard, and single, in-line memory modules (like those used in the Macintosh). It's unclear to me whether the company will have a different version of the ST that also includes its new blitter chip (which produces very fast, very high resolution graphics) or whether it will make that chip standard. Atari is also working on a Unix box (packaged in the same case described above) that would turn the ST's 68000 processor essentially into a dedicated graphics processor and unload the logic onto its own 68020 or 68030 processor. The proposed pricing for that Unix box would be $1,000, which along with the $1,500 or so for the two-megabyte 2080ST and whatever a reasonable monochrome display might cost, would turn Atari into a pretty

competitive workstation manufacturer.

(Don't take any of this as gospel. Although I've seen
engineering drawings and prototype boards for most of it,
with a Tramiel-run company you can't always tell whether a
computer in the lab will ever reach the marketplace. By the
way, we won't have Sig Hartmann to kick around at the next
SPA meeting: Sig is now working on calling on large
companies to pitch them on buying STs and future products.
From one tough job to another.)

Yeah, that IS a problem. In my efforts to write a program that will
later, upon an interrupt (say alt-help), stop the running application,
I tried that and still got bombs. Perhaps because I tried to end that
interrupt handler with TERM (GEMDOS #0), so I'd never have the chance
to add the 46 back in. I tried both subtracting (or was it adding?)
and not, and got enough cherries for a pie!

For os9 communications, you might want to try kermit. It's available from
the normal kermit distribution channels, and from the os9 users group.
(Disk 48) I don't know if anybody has it available on ST 3.5" format.
I'd like to hear confirmation that it works on the ST, but don't know of
any reason it shouln't.

General Os9 discussion probably belongs in mod.os.os9 rather than
net.micro.attari16.

I am interested in learning about the availability and performance of
(cheap & powerful??) Pascals, preferrably Borlands Turbo, for ST's. Has
anybody got any good suggestions? I know, C is the way to go but I like
the more or less TOTAL programing environment that Borland has glued

together in their packages.

Thanks,

Mike

I couldn't resist replying to this one. The ST computers are GREAT machines
but they need a multi-tasking O/S SOOOOO badly. The features mentioned
above would port fine to the Amiga. My uEmacs on the Amiga can spawn off
shells, execute a make or a cc while I'm still editing, etc. That saves
me TONS of time (forget it if you're using floppies - i.e., doing mulitple
floppy operations, but with a hard disk... it's usable).

The trouble is... if Atari chose UNIX (which I highly doubt they will)
they'll have support nightmares, and the reason I highly doubt they will
is that UNIX is HUGE. Sure you MIGHT get a kernel and a few bits and
pieces to run on a 1040ST, but all the utilities? I remember laughing

when I played with an ATT7300 (UNIX box) which had 4% available disk
space upon powering up for the FIRST time! What use is that?

PLEASE don't construe this message as another "this machine [AMIGA] is
better than that machine [ST]", my point was that multi-tasking is
incredibly useful, not only for developing, but for application users
too, e.g: boot the word processor, then boot the spreadsheet as well!
With inter-process communication, you can have real time integration.

So what are the options for the ST? I read about O/S-9 - sounds good,
but is it reliable, efficient, etc? Anyone know what Atari's plans
might be? I mean TOS/GEM/etc doesn't cut the mustard right now I don't
think. Fixed limits on accessed directories!?!!? Fixed #'s accessories
and/or windows? Geeez... guess they use fixed arrays inside. Can you
say "lists"?

     Paul.

I have been trying to get a correctly functioning version of MicroEMACS
3.7 for about a month now. The latest experience is worth passing along.

I tried the download and uudecode on the ST with three different (posted)
decoders, and had a variety of failures, and not getting a functioning
ME3.7. Finally, after uudecoding on our VAX (bsd 4.2) I was able to
download a binary version and (taa-daa!) it came up fully functional.

However (here's the good part), while it runs beautifully, it expands
EVERY space to a tab character (Believe it!) I'm not sure what the
probabilities of this happening are but they certainly help one believe
he or she can win a state lottery.

Bottom line...could somone repost the encoded and (please..on my knees..)
sources?

     Just take a big documemt with no spelling errors. (Your lastest
doctoral thesis should do nicely). Then run it through a program along
these lines:
%%%

```
     WHILE NOT End Of line
          ( for each character in the line )
          IF character is white space THEN
               print a new line.
          ELSE
               output that character
     ENDWHILE
ENDWHILE
```

%%%

some of the objects since then....

Before I start building the resource file again, does anybody know what the limits of RCS are?

II A list of bugs!?
What about somebody starting a list of bugs in commercial products (including TOS and GEM)? This would save a lot of people a lot of trouble since you could inform yourself about problems, limitations etc, before you started a project (or even before you bought the program). Maybe this could even motivate some firms to get off the list.

Simon Poole

OK, guys, I have a few questions for anyone to try to field about the ST:

- Why "lazy" menus? I am constantly going for the top of a window and ending up in the menu bar. This causes a menu pull, and I have to go far away from where I'm trying to click just to get the thing to go away. Is there a way to turn this off (i.e., make it like the Mac?).

- When I try to (for instance) grow a window, sometimes the ST doesn't realize I've pressed the mouse button until the pointer is no longer on the grow box. I pressed the button while it was on the grow box, though (I'm quite sure). It seems like the button is checked only about 4 times

a second. Is there any way to speed this up?

- If I edit the DESKTOP.INF file so that one of the windows displays only *.PRG files, it works until the window is closed and reopened. But the window display remains d:\. This isn't that important, but is there a way to fix it?

- When I grow a window, the corner of the frame immediately jumps to the tip of the pointer, rather than tracking on the point where I pressed the mouse button. Is this avoidable?

- The Resource Construction Set allows creation of Alerts, but there is no call to run them. The form_alert call creates the alert from a text string instead. Do I need to write my own routine to run an alert from a .RSC file? (Incidentally, the RCS has a bunch of Alerts in its .RSC file, but doesn't use them, and apparently uses form_alert).

- Holding down the arrow in a scroll bar doesn't cause continuous scrolling (like on the Mac). WHY NOT? This seems like a very obvious thing to do.

- Nothing I've seen except NeoChrome (which throws away the user interface standard altogether) uses the right mouse button. The documentation doesn't talk about it. In fact, I don't think GEM supports it. Good thing it's there, huh?

- A large number of programs (for instance, GEM KERMIT) seem to look for their resource files (or something) on A:\. Since I have a hard disk, I'd really prefer they look on the current default drive. Also, everything seems to want to be at root. Subdirectories are virually useless on this machine. And don't create more than 40 of them (well, don't access more than 40 of them between boots). As far as I can tell, there's no way to tell the linker to look anywhere else for the .O files besides root. You can't append drive or directory specs to the files in the command line, and there's no option like -I in the preprocessor (CP68), which tells it to look "at a different drive" (but a directory spec worked there) for the #include files. Something tells me Atari didn't develop the software for this machine on itself.

- Since the desktop is sooooo difficult to use (compared to, say, a Mac), it would be nice if there were a reasonable CLI. Is there? The one I have (version 0.1) doesn't have a single error message, and no documentation. So far I can change the directory, ls, and run programs. Is there a copy command? Pipes? I/O Redirection? If I had a good CLI I could just pretend I've gone back in time and I'm working on a PDP-8 again. How about a CLI that launches GEM applications in GEM mode?

In case you're wondering, I'm not too happy with the software on the ST. It seems like a PC running GEM, not a small Mac. But, of course, it's not a PC (although why not, marketingwise, I'll never understand), it has a 68000. Running CP/M-68K (essentially). And GEM/VDI. And GEM/AES.

MicroEmacs, of course, is great. But doen't use the mouse (it's not supposed

to). Why isn't there an editor like Edit (for the Mac) available?

I'm slightly sorry to vent all these complaints, but I see very little to praise. What is this machine good for?

Anxiously awaiting any reply,

I remain,

Very annoyed at Atari.

-Eric

Summary: use malloc(), in Megamax or uCShell

[]

So there's one more reason NOT to use the GEMDOS Malloc() for intensive dynamic allocation. It evidently was NOT designed for that!!! (It was designed for the progressive installing of accessories & applications into memory, along with their workspaces, during a typical work session.)

If your program does many malloc() calls for small pieces of RAM, and then free()s them up (e.g. microEMACS stores each line of text that way, and makes a new copy if it gets longer!), then you should use your own malloc() that gets a BIG piece of RAM from GEMDOS and then manages it itself. One such routine is part of the Megamax library. Another is shipped with Micro C-Shell. DO NOT USE Malloc()!!!!!

A question: when a C program exit()s, does it clean up the malloc()ed space? This relates to the following:

Challenge: can anybody devise a way to stop a running program that does

not do any I/O (i.e. does not respond to ctrl-C), but WITHOUT rebooting!?
(I currently embed calls to keybrk() here and there in my loops, where
keybrk() is just a call to GEMDOS to see if ctrl-C was pressed, and an exit()
if it was... - that works but is ugly!) - I would like some program that
responds to an interrupt (say the alt-Help) and stops the currently running
application, in a clean way (no crashes or reboots, ability to do it
repeatedly in a session). I would like this ditty to be a separate program
that you run once and then it sits resident in RAM. I have tried such
a thing, with the interrupt handler doing an RTE to itself and then calling
gemdos(0) - but I get mysterious crashes after a few uses! Any ideas?

In my version of microEMACS I left the old putc/getc stuff in for other
systems but #if AtST conditionally compile an alternative faster disk I/O
system. It uses an 18K RAM buffer, and reads/writes it using the GEMDOS
READ/WRITE functions ($3F/40). (On reading, I first call SFIRST to find
out the length of the file, then I ask READ to read that much or 18K, which-
ever is less.) That speeded things up tremendously! I chose 18K because
it is 4 SS tracks or 2 DS tracks, evenly, and the DMA controller can
read whole tracks in one revolution of the disk. Of course, files start
in middle of tracks so I actually read about half a track at a time.
I guess that's why 36K proved not significantly faster, and even 9K is
quite good! (A better way would be to read the FAT, find out where the
track boundaries are, and read a full track at a time!)
For more details look at the file "files.c" on my umacs disk.

> If there are people reading this and longing for an "easy" language
> or interactive (but not reverse Polish) environment, let us hear!

You have just described me perfectly. Why can't we have a block structured language and an interactive programming environment at the same time?! The reason that Turbo Pascal and ACTION! are so popular is the integration of the edit/compile/run cycle into one environment. This could be taken a step further by creating an interpreter for development and a compiler for generating the finished object code. Right now I'm using Pascal and Modula II (I can't stand C's syntax). But, as soon as there is a block structured language available that allows memory to memory compiles (or better yet incremental compilation), I am going to switch to it.

HBASIC sounds like it could be good, but, I don't know if I would be willing to give up local variables, and complex data structures (does it support these?). It has been my experience that 90% of the execution time that a program uses is due to 10% of the code. Often this code is simple and highly repetitve (moving a block of memory for example). It makes since to implement this part of the program in assembly and the rest in a highly interactive (though possibly slower) language. HBasic just might do the trick.

John

p.s. Hurry up Clint. I'll buy ACTION! the second that it comes out.

  Has anyone been able to successfully call BIOS/XBIOS functions from interrupt handlers ? There was some discussion on this couple of months ago in the BIX section of BYTE and the final message said you should subtract 46 from "savptr" before calling the BIOS function and restoring the previous value of savptr before returning. The interrupt handler is supposed to ensure its own atomicity. Unfortunatly this doesn't work.

  I've also tried assigning savptr to my own buffer and making BIOS calls which doesn't work either.

  My application for this is to have Xbtimer() set up an interrupt handler which, at certain times, sends a byte (or two) out the MIDI port. But the usefulness of calling BIOS from interrupt routines is, I'm sure, pretty wide.

Please help !!

Just a quick note on some OS/9 stuff. I just got off the phone with
the nice folks at Microware and have a little news. They say that
FORTRAN for OS/9-68k (full 77 standard) goes to beta test in October.
Expected release date is Nov. 1. They said a couple of big FORTRAN users
have been after them for months, so now, said users have been tapped to
be beta testers. It's only fair.
I asked about the "COM" package, it cost $125 and does include a
terminal emulator. I will post a short review when ever I get it.
They also claim to be working on windows and some niffty graphics
software. Look for it at the next COMDEX.
Also of note, TLM (porters for Atari) say they will have the VDI
interface ready sometime the last quarter this year. That's all
the news for now.

Nf-From: mic.UUCP!gary   Sep 22 18:25:00 1986

We just purchased an Atari 520ST. What a machine! There are many things
about it that are excellent, bordering on incredible. However, regarding
communications, the ST has several difficulties, which may well be due
to my lack of knowledge (hence this posting). In addition to the ST, we
have several UNIX systems which can transmit data among themselves at
9600 baud via uucp with no problems. The ST can be tied into this network
as a terminal with no difficulty, but (BUT), transfering files and
,preferably, whole directories of data to and from the ST is VERY time
consuming.

1) Does someone have a method available to allow the ST to use a uucp
protocal?
2) Does anyone have any local networking suggestions that would assist us
in using the Atari ST as a part of our local network?

Kermit and Xmodem are fine as far as they go....but what about local

networks at a reasonable cost?

Ideas/suggestions that could be useful to everyone should be posted.

Thank you,

Flames and VERY specific suggestions should be mailed to:

Data Pacific (David Small) has finally started to sell the Mac emulator for
the Atari ST. It is called (Magic sack). They were selling it this
weekend at the Atari Expo in San Jose (9/20-9/21). They sold out the initial
supply of 200 in 4 hours and thereafter took orders to be shipped in 2-3 weeks.
Show price $100. They will sale them later for (~$130). They plan on
coming out with a drive modification that will read mac disks.

James Landay

I have no affiliation with Data Pacific.

(Sorry if this already got thru but I doubt it ... so here I go again.)

Hi there.
I have decided (after much mental debate and anguish) on a thesis topic
to complete my degree. Seeing as there is an incredible void in the
area of GOOD ST BBS programs, I have made that my goal. What I
desperately require of my fellow net-atarians are original and/or
good ideas/features that I could implement into the BBS. Any worthwhile
suggestion will be considered and, since I will be releasing the program
into the public domain, the more replies I receive, the potentially
better product you as a user will receive (for free even).

I have several ideas kicking around including (but not limited to)
kermit, x+ymodem, FidoNet compatible, VT52/100 fullscreen editor for
callers, and so on. It will be written mainly in Modula-2.
Thx again for any help,   George.

BTW the tentative title is OPUS. If anyone can come up with anything better
I'll be glad to hear from you.

<< gulp >>

I just recently acquired access to the net and heard about
micro-emacs 3.7 and Hack for the ST. Could someone please
e-mail or repost them? Or, failing that, tell me where I can
rcp them from? Thanks.

All those calls for a "faster" development language may be answered
by a new english product - FaST Basic, a good structured basic which
comes complete with a macro assembler, and Pascalish (anyone come across
BBC basic ??) Basic. It is supplied as a cartridge (answer to questions about
whether cartridges ever worked) and a couple of discs with demos, libraries
etc.. A multi window editor/run environment is included, and you can get
to gem in either a very high level way, or at the standard gem interface.

It is pretty damn fast : benchmarks (pcw - English mags std bmrks)

average -	PC AT (8Mhz)	6.8 secs
	Commodore 128	40.1 secs
	520 ST	1.9 secs

all sorts of fancy debugging facilities are available, and it has double precis
maths for anyone who needs it.

all in all it is a pretty good product. (and I dont have anything to do with
the company)

available from Computer Concepts
Gaddesden Place
Hemel Hempstead HP2 7EH
England

tel : 0442 63937 (inside england)

I believe they take orders by phone as well, educational discounts
may be arranged. Price is ninety pounds (english) .

I bought one of the Mac emulators, which is called a Magic Sac. (TM)

My experience so far has not been good, although I am probably the exception that proves the rule. (Don't draw a negative conclusion until you've read at least the last paragraph of this tale)

I bought the MS on Saturday (before they sold out) and also got some rom chips at the show. I took the whole contraption, as well as my 1040ST in to where I work and tried to use the supplied download program to download some software from my MacLisa.

(The package comes with a Macintosh program which, in cooperation with a GEM program on the ST will download an image of a Macintosh disk using the RS232 port. One of the misfeatures of Magic Sac, resulting from Apple and Atari using incompatible disk formats is that it requires its own diskette format, and none of GEM, Magic Sac, or the Macintosh can read each other's disks.)

After considerable effort, I was unable to copy the diskette, packed up and went home. Sunday, I returned to the show (costing me the price of another admission,) in the hopes of finding a solution. Dave agreed that the code won't work on a Lisa, leaving me no way to download a system diskette, and thereby no way to use the cartridge.

However, apparent help was present in the Data Pacific booth, in the form of Alex Leavens, who offered to sell me a 'starter set' of diskettes in MAGIC format, which would contain a system and finder image, a couple of Boston Macintosh users group public domain diskettes, and a diskette containing Red Ryder and Free Term. So, for a mere 40 additional dollars, I was set -- I thought.

I drove home, inserted the boot disk in the ST, booted magic, inserted the MAGIC disk with the finder and got a Macintosh bomb. I drove back to the AtariFest, and convinced someone at the booth that I had bad diskettes. I set down with one of the other Data Pacific people and used their ST to make sure I had a complete set of working disks. (Two of the four diskettes I had been given were bad)

I rushed home (Milpitas, by the way is about 30 minutes from the show site)

rebooted and sure enough got a 'welcome to macintosh' prompt. As soon as I saw the finder, I decided to make backup copies of my four hard won diskettes, so I went back to gem and formatted six magic diskettes. (You can't use the Mac's format routines, because they make hardware assumptions about the controler which aren't true. . .)

I rebooted Magic, got a finder, tried to copy, and discovered that there is a bug in magic which makes it impossible to copy files from one diskette to another on a single diskette system. (I haven't bought an external drive for my 1040, because I'm saving up for a hard disk :-)

Back in the car for the third time, and back to the show, where I talked to Dave Small again. Showed him the bug, which he said he would get fixed as soon as he got back home, and asked him if I could use his two diskette systems to make my copies, since I would still be OK as long as I had backups and working terminal programs to download with.

While making the backups, someone in the crowd asked if I had tried the terminal programs yet. So, we tried the various terminal programs that were on the starter disk, and sure enough, NONE of them worked!

My situation at this point: I can't download diskette images because the downloader doesn't work with a Lisa, I can't backup with a single drive system, and I can't download at all because the terminal programs don't work. I pointed this out to Dave Small, and he offered to return my money. I told him I would like to give him a chance to fix the problems that we had identified, and that if he could get me started, I would rather have the Magic Sac than the money.

Alex, who had been having trouble with other diskette sets also offered to return my money for the starter set, and I said I would also like to have a working starter set, rather than the money.

So, Alex is going to get me diskettes within a week, and Dave has four bugs I discovered (1: No single disk copy under GEM; 2: No single disk copy under MAGIC; 3: Broken terminal emulators under Magic; 3: No way to download diskettes from a Lisa) which he has promised to fix. And I'm going to borrow a 'real' mac to try diskette downloading from.

If Dave Small can fix bugs 2 and 3, I'm going to keep the Magic Sac just because of the amount of PD software for the MAC I'm going to be able to run.

(Data Pacific claims that if it runs on a LISA, it will run on Magic Sac, and I've got a lot of stuff on my MacLisa.)

Even though my weekend was shot, and the thing still isn't working for me, I have faith in the people that I talked with, and expect to be hearing positive things back soon.

I'll keep you posted.

Marty

A few weeks ago I bought a SH204 harddisk. After formatting and partitioning
into 2 logical drives with the HDX program I started to transfer lots of
stuff from floppys to the harddisk.
After some Megs' I realized that the desktop directory listing of the 2nd
drive was scrambled. Looking into the directory with a diskeditor I found
text (Grrrrrrrr). This text looked terribly like a file I transferred to
the 1st drive last.
To make things short, it was the file.
A quick view onto the partition information block (sector 0 of hard disk)
showed that HDX created two overlapping partitions.
Trying different partition sizes I found that HDX was only able to create
correct partitions if I selected one of the predefined partitioning schemes
of the menu.
Did someone have similar problems with HDX ?

Hi Marty,
  thanks for your response to my C-flaming.
You are quite correct in saying : on machine X to do job Y I use language Z,
where Z is hopefully the best langauge for the job. I agree with practically
all your statements, BUT WE WERE DISCUSSING LANGUAGES FOR THE ST and NOT
which language I would use on a PDP-11,IBM 30XX, Cray, CDC, VAX, uVAX,
Pro-380, Apple, ZX80, QL, IBM-PC ....

>   Further, C does have strong type checking, but it is voluntary
> (through the use of Lint,) rather than mandatory.

This is the standard answer of every C-programmer, the problem is: nobody
I know has a Lint for the ST.

> ...That is, C with a good debugger is easier to debug than Pascal with no
> more than compiler diagnostics.

Which good debugger on the ST?

C probaly is the best language in a UNIX environment, but we don't have UNIX
on the ST (yet?).

I had read that the AUTO folder and the Monoc
rome monitor do not get along
together.. I found this to be true when I downloaded BICLOCK.PRG from CIS
and tried to run it. By the way, the program is called BICLOC.PRG in the
ATARI16 forum under utilities. This is the program that is featured in this
month's ANALOG magazine.

Anyway, the program seemed to work fine until I tried to escape from it. There
was no way to do this. Does anyone have a work around? Perhaps tricking the
computer into thinking that it is in a different resolution...

Thanks in advance,

I am working on a database system for my 1040ST, and I have a question
about how to have TEDINFO fields inside a window. It is clear that
they can be placed in Dialog boxes, but how does one get that to appear
in a window.

The only way I can currently think of is to create a window with the
hight and width of a dialog box containing the Object tree, and
placing the Dialog box directly inside the window. Well, I would at least
have the window contain the dialog box completely. Is this the way to do
this?. Would the window created then not be able to move?.

Thanks for any help or hints you can give me.

>OK, guys, I have a few questions for anyone to try to field about the ST:
>
>- Why "lazy" menus? ... (i.e., make it like the Mac?).

   Ask the lawyers at Apple, Corp. (Weren't you around for the Apple vs. DRI discussion?) Anyway, there is a utility in the latest issue of STart magazine which claims to be able to make the ST do stuff "like the Mac".

>- Holding down the arrow in a scroll bar doesn't cause continuous scrolling
>(like on the Mac). WHY NOT? This seems like a very obvious thing to do.

(See above answer)

>- Nothing I've seen except NeoChrome (which throws away the user interface
>standard altogether) uses the right mouse button. The documentation doesn't
>talk about it. In fact, I don't think GEM supports it. Good thing it's
>there, huh?

   Is this a serious comment? I'll assume so and treat it as such.
   First off, there *is* a use for it that you can demonstrate for yourself, in the privacy of your own home. First, open two windows. Now, hold down the right mouse button. OK, double-click (left) on a file in the *non*-active

window. Whaddya know! A use for the right mouse button! Even ignoring that small but useful use, do you think there's a possibility that A) people may want to use it in their own applications, and B) there just may be some things in life that you haven't yet encountered? Good thing it's there, huh? It's sorta like the cigarette lighter and ashtray in my car; I sure as hell won't use 'em, but I'm sure there are a few people who would, and I'm not going to complain to the dealer that they're there.

>- A large number of programs (for instance, GEM KERMIT) seem to look for
>their resource files (or something) on A:\. Since I have a hard disk,

>seems to want to be at root. Subdirectories are virually useless on this
>machine. And don't create more than 40 of them (well, don't access more
>than 40 of them between boots). As far as I can tell, there's no way
>to tell the linker to look anywhere else for the .O files besides root.
>You can't append drive or directory specs to the files in the command line,
>and there's no option like -I in the preprocessor (CP68), which tells
>it to look "at a different drive" (but a directory spec worked there) for
>the #include files. Something tells me Atari didn't develop the software
>for this machine on itself.

   The above points are all good; they are either programming bugs or laziness, or the result of short-sighted operating system design. The linker and compiler I use are fairly good about allowing me to specify different directories for include files, source and object files, and library files. If you're the legitimate owner of a piece of software which you believe needs enhancements, write a letter to the company. I'm sure they'd be happy to make their product more attractive. Complaining to me won't get you far.
  The only thing I'd disagree with is the RSC files on the A:\ drive problem. All the programs I've seen, including GEM kermit, seem to look for the RSC file on the drive/folder from which the program is executing.

>
>- Since the desktop is sooooo difficult to use (compared to, say, a Mac),

>command? Pipes? I/O Redirection? If I had a good CLI I could just pretend
>I've gone back in time and I'm working on a PDP-8 again. How about a CLI
>that launches GEM applications in GEM mode?

   Oh, the Mac again, eh? Well, I'll explain a little better. The fine, original-thinkers at Apple made the Macintosh in the image of a Xerox icon-based OS interface. The folks at DRI did the same. However, one of those companies was bigger, and had more money to spend on lawyers, so they made the other company make some small yet significant changes to their OS interface, so they wouldn't have the same "look and feel" as that original Xerox product. Life is strange, no?
   As far as CLI's go, are you complaining about a PD (i.e. free) program? If not, are you complaining to *us* because *you* wasted money on a product that doesn't deliver what *you* think it should? Anyway, Michael Beckmeyer's (sp?) Micro C Shell seems like a good, Unix-like CLI, complete with pipes,

I/O redirection, a copy command, and a host of other Unix-like commands.
Look into it, unless you don't want to have to pay a nominal fee (~$30)
for a very useful program.
   And as for PDP 8's, go back in time and see how much your PDP 8 costs.
I think too many detractors of reasonably-priced personal computers expect
them to be MicroVaxen, not pc's. If you want the capabilities of a Vax
buy a Vax. But don't complain when you buy a $500 machine and it can't
outperform a Vax.

>In case you're wondering, I'm not too happy with the software on the ST.
>It seems like a PC running GEM, not a small Mac. But, of course, it's
>not a PC (although why not, marketingwise, I'll never understand), it has
>a 68000. Running CP/M-68K (essentially). And GEM/VDI. And GEM/AES.

   The ST is maturing, in both hardware and software. The Macintosh has
a good 2-year lead on it. If you need a monochrome machine that has
software now, and a user interface you like, why didn't you buy a Macintosh?

>I'm slightly sorry to vent all these complaints, but I see very little to
>praise. What is this machine good for?

  I dunno. Who would be dumb enough to buy a useless machine?

Since Atari now has a FOUR meg machine (in Europe) what's the problem :-)
Also, someone at the recent San Jose Atari Show had a prototype 2 meg
upgrade for the 1040, so in a few months we'll all have the extra meg
of memory that we could not think of a use for before and now can't live
without!

Dave Small of Data Pacific just called about my problems with Magic Sac (see my earlier text for details) and has indicated that:

1) The bug which roached the terminal driver was the result of a last minute attempt to improve something, and has been fixed.

2) The bug in copying files between diskettes on a single drive system is a problem in the Mac OS, but they will be doing a workaround in the near future.

3) He is going to do a 'copyaa' program to allow backup of diskettes under GEM on a single disk system, and that will be done soon.

4) The bug in the LISA version of the code will take a little longer, but they are getting a LISA sometime this week, and will fix it.

He promised to send me diskettes with the updates as soon as he can get them, and is going to make arrangements with local dealers to get updates out in general.

Meanwhile, I should be able to borrow a Mac this weekend and test out the rest of the system.

Marty

Summary: The editor should be SMALL!

[]

When I use Megamax C on a 1040ST, I set up a 576K RAM disk which nicely
holds the compiler, linker, libraries, and a bunch of source and object
files. I hate waiting for the disk, so I also have a communication
program in the RAM disk. The RAM disk cannot be much smaller for serious use.
In what's left (about 200K after GEMDOS and Micro-C-Shell take their tax)
I can run the compiler OR the linker OR the editor, one at a time.
Using microEMACS I can edit 2 or 3 source files simultaneously (about 20K
each) before I run out of memory.

     Everything just fits and I DON'T WANT A BIGGER EDITOR!

I want a smaller one! My version of microEMACS, which includes decent
word wrap/fill and bracket-balance check, and RESIDENT help screens,
is about 42K. Small for "real" editors, but a lot bigger than, say,
the 4K RAM-resident screen editor I wrote for the Apple II - in machine
language. The communication program I usually use on the ST is the PD
"XMOTER(M)", because it has just the features I usually need, and is less
than 5K long!

Whatever happened to the kind of operating systems that used to run in 6 or 8 K bytes in a PDP-11? Things like RSX-11M? We used to do wondrous things in 32 K bytes including EVERYTHING. When we went to 65 K it was sheer Heaven (especially after DEC found and fixed those silly BPLs that should have been BHSs and caused a lot of their own software to crash when the addresses went negative all of a sudden).

What I'm trying to say is: megabytes are nice, but why not USE THEM for something USEFUL rather than squandering them in overgrown operating systems and inefficient applications programs? Reminds me of IBM's universal answer for all problems: buy more memory. Buy a faster processor.

Just think what you could accomplish with a 68000 and even 512K of memory if you programmed the way they HAD TO when 65K was a BIG machine!

Summary: Apparently not

[]

Somebody from Megamax posted here a while ago a notice that a free update of the Megamax C Development System is available. I finally decided it might be time, and called Megamax. The person who answered the phone never heard of such a thing. It was a phone-answering/sales person, though, and nobody else was around (it was rather late Friday afternoon).

IS there a Megamax update? What is fixed in it? Any voices from the mount?

David Beckmeyer was demonstrating a Unix-like environment, complete with multi-tasking and multiple logins on an ST this weekend. Granted, you needed a hard disk and 1k memory to run it without things dragging, but at least someone has done it.

Beckmeyer's multi-tasking C shell retails for $99.

I never could stand that manager, so I tried to use the compiler and linker from PP with Micro C shell. Worked like a champ! One question for all you experts out therte in Netland...The pascal compiler calls itself ST Pascal, and it allows options from the command line. Anyone know what those options might be?

Oh, yea, one other disgusting thing. It expects to see PASGEM and PASLIB in root. Well, can't win them all.

> Show price $100. They will sale them later for (~$130). They plan on
> coming out with a drive modification that will read mac disks.

>

     I read several other messages on another net from people who said they bought the Mac Emulator box at the Atari Expo in S.J. They also mentioned that they went to another booth and purchased the Mac ROMS. Is this possible? I don't recall hearing about Apple authorizing the third party sale of their ROMs. Could someone fill me in on this?

Yep, had the same problems you mentioned. I had to reformat twice, but
I still have a nonstandard partitioning. I recommend you use the bad block
option as soon you have formatted you disk. This will find something about .2
percent of the disk to be bad.
I'm running for 1.5 months now without any trouble.

With the old archives being moved off line, I thought that the list membership might like to have an update on what is available. The following files are in directory <info-atari> on SCORE. They can be FTPed from ARPANET, etc. Unfortunately, they are not available to bitnet. I am trying once again to find a bitnet host that will put at least part on line.

While I'm updating your status information, I thought it would be
helpful if everyone re-read the welcoming message which sets the
ground rules for info-atari:

Welcome to info-atari{8,16}. You may send messages to all
"subscribers" by addressing it to either or both addresses at
SU-SCORE. Administrative messages should be sent to
info-atari{8,16}-request.

All messages should be in good taste. Commercial messages and
advertisements are not permitted. When answering a question, please
consider carefully whether the answer should go to the whole list, or
just to the person who asked the question.

All messages are in the archives. In addition, some contributed
programs are also there. The archives are in [SU-SCORE]<info-atari>.
The archives are stored in TOPS-20 message format (MM is the mail
handler used). After you have obtained a copy (see below) your mailer
may be able to read these files. Probably not! I would suggest using
an editor to search for "Subject:" or whatever you are interested
in. See the file MM.FORMAT in the archives for a description
of how the file is organized.

If you are on ARPANET or MILNET you can FTP from the archive. I don't
know how you can get the files otherwise.

    The following ground rules should make the use of this (or
of any other) mailing list much easier:
 . never send a message that a totally irrelevant to the mailing
   list's purpose to a mailing list. This especially includes
   any expressions of irritation at another list member.
 . never forward a message that is totally irrelevant to the
   mailing list's purpose to a mailing list.
 . when replying to a message on a mailing list, reply only to
   the sender of the message unless the reply is of interest to
   the entire mailing list.
 . avoid inserting the message being replied to in a reply,
   especially in a message going to a mailing list. The
   context of the reply should be clear from *your* reply and
   from various mailer functionalities such as Message-ID.
 . when replying to an earlier reply that violates the previous
   rule, ABSOLUTELY DO NOT make matters worse by adding your own
   violation.

Uniterm is a great program, and it is a great relief to have my ST
working as a terminal with graphics emulation. However, I need to
rewrite the termcap and terminfo files, if only to take out the unused
initialization strings -- if anyone has already set up the necessary
files, I would appreciate copies (or you may want to post them).

One problem I have run into is that Uniterm does graphics plots just
fine, but the labels do not appear -- they only come out when I return
to the text screen. Any solutions? (I am using a colour monitor.)

About four weeks ago I "accidentally" bought an ST. A local store
had a grand opening of their second location, and they had 20
Mono/SS systems at $399. No way could I pass that up! Even at this
ridiculously low price, it took all my spare cash and then some, so
I'm stuck with PD and the bundled software. Now to the point, 1st
Word seems to be a reasonable low level word processor, but I've got
a problem with it talking to my SG-10. I re-worked the driver,
installed it, moved it to root and almost everything works.
What doesn't work is the NLQ select at print time, no matter what I select
when it asks me, I always get draft quality. I can't find anything
in the driver that allows me to set the NLQ escape sequence by itself,
it works ok when I switch to NLQ in the document, but that's not
what I'm looking for.
I suspect this has already been covered, but I wasn't really paying
attention. I hadn't really planned on buying an ST yet, but it
couldn't be helped :-) If anyone knows of a fix, I and about six
others in our local ST user group will be very happy to know what it
is.

So GNUEMACS is too massive for the ST... Is there a REALLY decent editor
out there for the ST that an EMACS addict can live with?
Micro-Emacs is nice and powerful, but it ain't EMACS. (Actually, the only
real EMACS is the original one written in TECO. GNUEMACS is considered an
EMACS-like editor.)

For lack of a better CLI, I need an editor that I can live in. It should
be able to do more than just compile a program or spawn a CLI, it should

be able to perform directory editing (DIRED), real macros and simple
file filtering. Yes, I know..I am power mad..I want to much, overkill, etc..
but hey, I can't live in the windowing world of GEM anymore. I spend most
of my time editing, and unless I can fire up a small editor whenever and
wherever I want in an application (without reloading the file each time).

Any interest in implementing TECO on an ST? Is this a sick idea?

People should realize that some of the nicest features of GNUemacs
are things that would be lost in a port to the ST: compiling from
inside an edit session, shell windows, and filtering regions
through commands are obviously not going to work without
Unix multitasking. It's still a nice editor, and without those
features it might be small enough to fit...

Summary: Please let's have a disk version too!

[]

Putting a language on a cartridge seems popular to some. It is certainly
a potent version of copy protection, which doesn't really need a back-up.
My gripe is that it is not as easy to swap cartridges as disks, so I'd
rather put something in the cartridge port that would be universally
useful and will be left there all the time. Sort of like that clock
board, although luckily we can (?) now put a clock inside the box.
My own favorite candidate is a floating-point coprocessor board.
In any case, hardware, not software. (Never mind what Atari thought
it made that connector for - and damn the stupid write-protection of
the cartridge address space!)

A program in ROM will also have bugs left in longer (or forever) - e.g.
Applesoft BASIC. (Hopefully not TOS...) Also, some people like to modify
their software! (I, for one, have modified the Apple II monitor ROM
and will probably redo TOS eventually if Atari doesn't.) Disk versions
(unprotected) are a lot easier to modify = user friendly.

Then of course, if a certain language is your DAILY working environment
you would like it in ROM. How about an OPTION of getting it on a cartridge,
in addition to the disk version, which is more appropriate for other buyers?

BTW, FaST BASIC sounds sort of like HBASIC. Is it incrementally compiled?
It would be interesting to compare them, when HBASIC comes out.

According to some postings in other groups, the site 'vecpyr' went off the
air one day and has not been heard from since:

Based on information in the uucp network maps, I offer the following
suggestions...

UUCP:

...!pyramid!atari!neil
...!lll-lcc!atari!neil
...!hoptoad!atari!neil

ARPAnet:

atari!neil@lll-lcc.ARPA

Note that the administrators of lll-lcc and hoptoad are known have a low
tolerance for mail that they feel is inappropriate or excessive being routed
through their systems...

One thing that might help with uudecode problems is to have the following
included in every uuencoded file (before the begin line of course!) or
posted in another message:

1) Size in bytes
2) CRC and/or linear checksum of binary (uuencode has no checksums!)
3) systems tested on (color/mono, tos-in-rom/tos-in-ram)

This way we can determine if uudecode worked correctly.
Some problems may not lie entirely with uudecode. I think uEMACS 3.4
did not work on mono systems (3.7 does with hres50).

Btw, this is assuming there *are* CRC programs already written. I haven't seen one and have no C-compiler (yet). Perhaps a good topic to discuss on this mailinglist is what public-domain crc checkers are out there and how interchangeable they are.

Hope this helps,

I was giving myself fits trying to uuencode a file on the VAX with output into another local file until I finally figured out that the argument called 'destfile' in the uuencode manual is just the string to put as destination file name in the 'begin' line.

If you leave out this string, uuencode apparently takes the first argument to be that string and assumes that you meant to type in your binary file at the keyboard. (Sounds like a silly assumption to me, but I didn't write uuencode.)

To uuencode into a local file, I found the following syntax to be necessary (or at any rate sufficient, which is sufficient!):

```
uuencode inputfilename anystring >output filename
```

It is useful to use for the string the filename you want to put the thing in when it gets to the final destination. For the local output filename, I have settled on .uue as an extionsion.

I thought some of the other people currently preoccupied with uuencode might have run into the same problem so I hope this helps.

Swiss Data - Rumours

This morning I visited the local computer exhibition Swiss Data in Basel.
What I actually saw on the stand of the ATARI general distributor SAMA was
- a sign announcing the 2080 STf (I'm not quite sure about the STf bit) with 2 MByte RAM,
- a sign announcing the 4160 STf with 4 MByte RAM,
- a demonstration of a 1040 with blitter chip against a 1040 without,
- a prototype of the MS-DOS/IBM-PC emulator running Multiplan.

Being rather suprised seeing all this and ATARI USA being rather quite about future products I got hold of the senior salesman there and asked him a few questions (this is not a quote, just a summary of our talk!):

When will the 2080/4160 be avaiable? End of the year/next spring together with a laser printer. Packet price < 10000 SFr.

(The idea seems to be that the laser printer will not have its own controller but will use the ST -> that's the reason for all that memory).

When will the blitter chip be avaiable? Real soon now.

(It seems the first batch of blitters had a design fault and the chip had to be redesigned, the one I saw was supposedly a new one, it worked ok as far as I could see)

Will old 520/1040 ST's be upgradeable somehow? Perhaps.

I couldn't check the MS-DOS emulator out, since the only program they had was MulitPlan and that looked ok. The blitter chip did seem to speed up graphics quite a lot, but I didn't see any demonstration of plain text or a real commercial program.

II Receiving Mail on IBM mainframes - Moshe Braner's letter

Moshe is quite right about receivng mail on IBM mainframes, I always get a personal copy of any mail from a SIG on my virtual card reader (this is using VM/CMS, I get nightmares thinking about getting mail with MVS).The only resonable way to read mail is to use a fullscreen terminal and RLIST, but all operations (discarding, receiving etc.) on any files are very very permanent (see next part III of this letter).

III Pascal vs. C

I'm sorry I don't know who actually wrote the original letter (I accidently discarded it , see part II of this letter), but in one of the last postings somebody claimed that Pascal is more restricting than C. Sorry but that is called in German "Aepfel mit Birnen vergleichen", C is NOT a high level language, Pascal is! A high level language with strong typing and no access to low level facilities will always be more 'restricting' than an assembler or C. Choose the correct language for the job you want to do (this doesn't mean I would choose C to do ANYTHING) and don't forget the time you gain thru not being 'restricted' by Pascal will be lost debugging your

C program.
If you wan't to compare C to an other language compare it to Modula II.
I'm sure there are not many things you can do in C you can't do in Modula II and you have the advantages of a low level language combined with a high level one.

IV UniTerm - Problems with Tek mode

All those people which have trouble with the Tek mode of UniTerm, try starting out from the Tek4010 mode (I've changed the switching logic in the new version), if the problems are still there, use filecapture to collect the sequence which is causing trouble and send it to me.

I've finished the updated Version of Uniterm, bug fixes include:
- VT102 insert line and delete line work correctly now
- shifted function keys work (this was due to a mistake in ST Internals Data Becker / Abacus, the shifted function keys generate different key codes than the non shifted ones)
- GIN mode really works now
- Tek command decoding has been fixed, probably nobody noticed it anyway
- repeated use of RESET TERMINAL doesn't cause a Stack overruns Heap message anymore (this was due to a bug in the Delete_ Dialog call of CCD/OSS Pascal)
- Tab works correctly now

changes from Version 1.2 include
- SLE buffer now 20 lines large
- GS received in VT102/VT100 mode sets the mode to tek alpha mode and UniTerm stays in Tek mode until switched manually back

enhancments include:
- VT52 mode
- a bit of Pericom compatability

I've just got one problem: shall I post it to the whole net or not? Consider following facts:
- I probaly already made the UUCP top 25 poster's list last time and I hate thinking of all those large telphone bills
- I've got something like 40-50 requests for the updated version
- I have a lot of trouble sending anything to sites which are not on BITNET or arpanet, typically I can't get through to the site I want to on 9 out of ten trys (maybe someone could tell me what I doing wrong?)

Any comments? Could someone give a estimate on how many people get this mail? How much does it cost?

I would love to see the reaction of some of you language experts to OSS's ACTION! for the Atari 8-bitters. It is structured, but reputedly so close to as fast as Assembly language as makes the difference not terribly significant. And it compiles faster than anything else known to Man (or Woman, for those who choose not to topologically identify the two lexical items for this purpose).

If we are REALLY lucky, maybe OSS will come out with an ACTION! compiler for the ST. Then maybe the DoD will select it to replace ADA!!!

(P.S. - in English the idiom is "comparing Apples and Oranges", but personally the pears sound tastier anyway.)

I have version 1.03 of the program. Look under the style menu and choose spacing. If you have the text mode turned on (wrap and wp), then the doc will auto double space when it wraps but not when you type a <CR> yourself. In fact, about printers, I can't get my printer's on-board switches to do anything for spacing and pitch. 1st Word initializes the printer at startup and makes it space the way the program wants. I edited the configure file. But the codes for the minimum move strings (horiz and vert) were confusing. The last number in the string, the parameter, seemed off, but when I changed it to values closer to what WordStar uses for the same printer, the printing really looked strange. Does anyone know what HMI string to use to set a Brother-HR15 to 12 pitch?

Another question: Is there a scribe type text formatter for the ST. example: @quotation{This is a sample nothing more. This is a sample nothing more. This is a sample nothing more. This is a sample nothing more. This is a sample nothing more. This is a sample nothing more. This is a sample nothing more.}

becomes

> This is a sample nothing more. This is a sample nothing more. This is a sample nothing more. This is a sample nothing more. This is a sample nothing more. This is a sample nothing more.

I'd really rather use uEmacs for all of my writing and let a batch formatter take care of the drudgery.

Summary: Any 1040 or DS discounts?

[]

All the great discounts seem to be for 520ST+monochr+SSdisk. Anybody
knows about a cheap source for the basic 1040ST package (it is $850
right here at the local dealer - when he can get any...), or for the 520ST
with a double sided drive INSTEAD of the SS, or for DS add-ons?

(I personally cannot stand the thought of being limited to half the disk
capacity. I waited long to get my 1040!)

Generic (i.e. not specifically for the ST) double-sided 3.5" drives are
now available for about $100 some places. Can anybody tell us how to
connect them to the ST? Is it just a matter of finding the $%#@& connector,
and the pinout on the back of the drive? (And getting a power-supply for
the drive - or can we run it off the 1040ST assuming we don't turn more
than one drive at a time?) Or is there more to this black art? Is the
$200 to $300 otherwise charged reasonable? (If the cable is $30 and the
PS/box is $30 then $250 for the finished thing may be OK...)

I have two questions to pose to the net:

1) A friend of mine has a Panasonic T40 Electronic Typewriter with a K100
   interface. He's trying to get it to print from First Word, first
   trying both the daisy wheel drivers that come with the program.

Unfortunately, neither of them worked. Does anyone know of any printer driver or modification of one that could be used with this electronic typewriter?

2) Is there any way to make files from, say First Word, compatible with Mac files so one can print the result to a laser printer? Has anyone tried such a file transfer?

BTW, Atari claims that they will be bringing the laser printer out around 2nd quarter next year...

Thanks in advance,

Cathy

Both the Sept. & Oct. issue's of ANALOG include a user group list, also a recent issue of ATARI EXPLORER had a list. You can also send a SASE to Atari's user group coordinator and they'll send you a list.

Using the untranslated addresses as the RAS addresses and doing the MMU
address translation before the column addresses are needed for CAS sounds
pretty general to me. I am sure the process Andy Bechtolsheim patented is
quite a bit more specific. A patent cannot be granted for a general idea.
It requires a specific implementation of an idea, either in a device or
process. Think about it. Without that provision patents would stifle
development. They are intended to do just the opposite. A patent is
supposed to protect the inventor of a process from those who would use his
work as their own. But it is not supposed to prevent people from using a
concept the inventor has brought to light in their own inventions, so long
as they don't plaigiarize from the original work.

I just saw a note on a local BBS that NITE LITE Systems, who sells a
well-known BBS for the Atari computers, is selling the new fully Hayes
compatible 1200-baud modem (Model 1200HC) for $149.95 for a limited time.
The offer expires this Friday, Sept. 19. They also have the older Model 1200
(partly Hayes compatible) unit for $84.95.

Their address is NITE LITE SYSTEMS, P.O. Drawer "R", Billerica MA 01821.
They also run one of their own home grown BBS systems, now on an ST, by the
way, at (617) 663-4221. The SYSOP and proprietor of NLS is Paul Swanson.

The NITE LITE BBS has been around awhile for the 8-bit Ataris, but ST owners
may be interested to know that an ST version is available. Info on this
product is available on the BBS mentioned above, also. In particular, callers
get to try it out from the remote end!

I can't quote the passage, but somewhere in the latest (Fall) STart mag, BI fellow mentions that there is some kind of problem with the backspace key in 1ST WORD and Thunder; he said that there is an option in Thunder you can disable...oops, found it: page 95, "Developer's Notepook: Transportable GEM (IBM to ST)," Mark Skapinker.

> "The newer versions of 1ST Word do not allow the Backspace key
> to buffer characters....This caused problems in the speed that
> Thunder! deleted characters..."

I swear somewhere in the article he mentions an option to toggle. In case you need BI's address,

Has anyone been able to compile a desk accessory program using Lattice C?
I have tried simple tests, and conversions of programs from Alcyon, but no
luck. Is there something I am missing?

Also, I have a copy of UUDECODE written in Lattice C that I got with a GEM
Kermit. THE THING JUST WON'T WORK.... I get the messages: Short File and
No End Line . (Yes the files do really have 'end' lines.) The resulting
executables that are produced simply return me back to the desktop. If anyone
can respond to this problem, or have a UUDECODE that they know works...I
would appreciate your mail.

P.S.
    Micro-Emacs is fine..But when is some brave soul with a ST and hard disk
    gonna tackle Richard Stallman's GNUEmacs? It ONLY consists of 1 Meg of
    source code in C, (not counting the xtra Lisp functions).

Hi,

     I'm the original author of the 'Pascal is more restrictive than C'
comment, and I would like to reply to your response to my comment.

The standard definition of a high level language is that it is one in which a single source statement typically translates into multiple assembly statements, as opposed to a low level language in which the translation is usually one to one.

By this definition, C is a high level language.

If you chose to be more pendantic, you can claim that the level of a language is dependent on its degree of data abstraction and strong typing, in which case neither C nor Pascal qualify as high level, since Ada has a considerably higher level of abstraction and typing than either language.

Also, C is very similar to Pascal in its ability to handle data abstraction, having all of the facilities Pascal has, except for the set data type, which is replaced by the ability to perform seperate compilation.

Further, C does have strong type checking, but it is voluntary (through the use of Lint,) rather than mandatory. Also, it is relitively straightforward, although painful, to avoid strong type checking in pascal by using variant record types. It just makes for cumbersome code.

Also, correct use of C produces more portable code, since there are far more dialects of Pascal then there are of C. (Although the people producing microcomputer C compilers are trying to remedy this :-)

As to your comment about speed of debugging, I would disagree for empirical reasons. I have been using Pascal since I ported the ETH compiler to RSTS/E on an 11/70 nearly a decade ago, and have used it for some fairly large applications, including an APL interpretter, a Pascal compiler, and a Chess program, as well as the required language in the compiler and operating system courses I have taken, and the language of choice on both of my own personal computers.

On the other hand, I have been using C since I ported 6th edition Unix to an 11/23 at about the same time, and have used it for some fairly sophisticated applications, including C compilers, graphics packages, performance measurement and network software on computers ranging from 68000 machines to Cray 2 supercomputers.

And, (to make the picture even more complex) I have been using Fortran since 1973, when I first learned it on an IBM 1620, and have used it in various engineering applications ranging to a mine design package which runs on large CDC systems.

It has been my experience with these (and other) languages, that the amount of time required to debug a problem in a real system is relitively independent of the source language, but highly dependent on the support environment. That is, C with a good debugger is easier to debug than Pascal with no more than compiler diagnostics.

Modula-2's disadvantage is that it is far too sophisticated to use on many small problems. Using M2 to write a typical unix filter is a lot like trying to whittle with a machete - the amount of work you do is far greater than what you would have had to with a carving knife.

As long as you are bringing new languages into the picture, why don't you program in COBOL? (:-) It is certainly high level, it has data abstraction, and it has strong typing that is even more difficult to subvert than Pascal's.

Chosing the 'one right' language is a religious decision; most people being brought up to believe in the first one they learned or its more popular successors.

I have been fortunate enough to have been forced to use a large number of languages, and am truely agnostic in this area. If I want to do a toy expert system, I use LISP. If I were going to write a real one, I would use one of the expert system writing languages. There are a whole family of related languages for things like algebraic manipulation and symbolic calculation.

If I want to do almost anything on a Unix system, I do it in C, since C is well supported and integrated in most Unix environments.

If I want to do fast vector calculations on a supercomputer, I will use Fortran, or if it's not fast enough, the machine's assembly language (and get help from local experts in tuning the code.)

If I had to do a payroll on an IBM system, I would do it in COBOL.

If I had to manage a very large project (more than 1 million lines of code) and there was a good implementation available, I would try Modula 2, unless it was for the department of defense and ADA was available.

If I want to program my MS-DOS pc, I use Turbo Pascal, because it is reasonably good, and very cheap.

If I want to program my Atari ST, I also use Pascal, for the same reason.

However, Pascal will fall on both of these systems, because I will eventually have to buy a C compiler to support all of the public domain software I can obtain in C for each system.

Marty

This is a follow up to the UUDECODE program in ST BASIC I posted to this BBS.

Additional notes:

1. The UUDECODE program does append spaces to the end of the line if it thinks they were removed in transit.

2. The file length (in bytes) is always a multiple of 45. The extra bytes are filled with garbage and hopefully ignored. (This is not standard UUDECODE.)

3. This being a BASIC program, it is slow. Typical time, about 1 sec per line of coded info (using a ram disk). [about 40 minutes for UNITERM, which was 135,000+ bytes before decoding.]

4. I had trouble UUDECODING the MONST program posted recently here. It turns out there were 2 carriage returns at the end of each line. Editting with either UEMACS or 1ST WORD fixed the problem (enter editor, make no changes except to save the file). The problem was probably caused initially by me using KERMIT incorrectly.

I have received several messages from network servers warning me that my original message was not delivered. If anyone needs a copy, let me know. Also, if anyone finds any bugs and or helpful fixes, let me know.

Thanks, and good luck!

The difficulties ARE great. Code on the ST is relocatable at load time, not position-independant. Most reasonably long jumps will be expressed as absolute jumps once the code has been loaded, and

accessories have also had a chance to run once until their 'event_multi' call, and here they are free to look at their location in memory and do other rude stuff. So sure you can boot out accessories, but you can't move and pack the others to use the memory for very much. The best solution is one which can reset the memory pointers, clear the menu register, and then allow you to selectively re-install the desk accessories you want. This is just short of a reboot, and it may be very awkward to not go the whole way. I'm not sure how I would go about the re-install at all, since the best way would be to read the BIOS and GEM source code and be able to mimic what happens on a reboot with accessories, and *that* information is likely proprietary.

Keywords: finally available

It looks like the much-awaited Supra 30 meg disks are finally here, since the unit I had ordered from Computer Mail Order arrived today. It comes pre-formatted and partitioned as 3 10-meg drives, C:-E:, although you can change the partitions to suit your needs. Interestingly, when running the partitioning/formatting program, the type of disk is NOT "Supra 30meg" but a Seagate unit with an Adaptec controller. I suspect (but am not yet sure) that the unit is a 20meg stretched via Adaptec's RLL SCSI controller.

> 1) Hard disks: I'm interested in getting a 20Mb hard disk. I've heard that the Supra hard disk is superior to the Atari hard disk, but I do not know any more. How do the two disks compare in terms of
>
> 1) Speed
> 2) Convenience, ie. size, installation.

I have the Atari SH204 20 meg hard disk. The speed is wonderful (though I don't know how it compares with the Supra). Overall, I have been quite pleased with its operation except for the following:

(1) The cable is too short to permit the disk to be placed at the back of the table and still have the front panel face forward. So I have the disk sideways with its back end (where the connector is) close to the 1040. But of course, there isn't much to see on a hard disk anyway.

(2) Much more serious are limitations mentioned in the owners manual; in particular, that you should not have more than 40 directories total in all partitions and all devices attached to the ST. Apparently this restriction is due to some sort of bug in TOS. I don't really understand why or how the ST even knows how many folders I have several levels down in the directory tree, and indeed, one can apparently exceed the 40 number for some period of time without any trouble. But the bug, whatever it is, is real, and the result is a trashed partition on the hard disk. I rebuilt my disk 3 times over the weekend before finally taking that restriction seriously. (I had been using it for a month without problems; the trouble only started when I added some new software that caused several new folders to be created.) I would really appreciate hearing from anyone who has any better information about this bug and what to do to prevent it and/or recover from it.

(3) The software that comes with the hard disk does not permit booting from it. Instead, one puts the driver on a floppy in the AUTO folder and then boots from the floppy. Desk accessories are loaded from the hard disk, but any AUTO folder on the hard disk is ignored. Neil Harris announced a few weeks ago that TOS will in fact boot from the hard disk if the appropriate boot sector is written on it. He indicated at the time that Atari had software to write the boot sector and was currently using it in-house and that they would release it if no problems developed. (Neil, are you still listening, and is it soon to become available?)

   I've gotten on it with no trouble, most of the time. However, on quite a few occasions, I've had the problem you describe-- a connect, then nothing. It happens maybe 1/4 of the time. It's gotta be a problem at Atari's end, since I call all sorts of other BBS's with no problems.

If the HR-15 is like the HR-35 all you need to change is one character under "Misc. Configurable Variables". Change the second "C" to an "A". The row should read "1, C, 28, 1, 0". It's the hex numerator of the fraction n/120. Whatever, it works. HMI doesn't need to be changed.

I've finally decided to buy a 520ST, but first I'd like someone to assuage (whoa!) my doubts about one thing: what is the likelihood that, with the widespread availability of the 1040 and the imminent release of a TT (or whatever you want to call it), the poor little 520 will be left by the wayside? I've already run across a couple of programs that say "1Meg recommended." Will that soon become "1 Meg required"?

Ditto about the single-side drive: I'm buying the cheapest system I can (the monochrome, 1SS drive from 47th St Photo), because it's all I can afford. Will software continue to be available on SS disks? (When was the last time you got a disk for an IBM PC that was single sided?) And, about the price, does anyone have comments about the $495 package from 47th?

Thanks for letting me ask these questions. I appreciate any comments.

All you have to do is to change your printer driver to send 2 linefeeds
instead of one. If you bounce between single and double spacing alot you'll
probably want to have two printer drivers and swap in the one you want.

Sorry, can't help you with the price rumor.

You can copy the .prg and setup files to any disk (even ram), the trick is
that you need the original disk in drive A when it loads - even if you boot
from another disk.

I use PC/Intercom alot, my beef is that there's no way to do any local disk
utility stuff (like getting a directory listing).

Occasionally we have a glitch and you won't be able to get through. We check
the BBS at least once per business day, so the answer is to try again the
next day and you ought to get through.

By the way, the main number for the Atari Base BBS is 408-745-5308. The
number you listed is the 3rd of 5 lines. When the board is busy, calling
the main number gives you 5 chances to get through. The 3rd number will

ignore the first two so you only have 3 chances.

The 40 folder limit is inherent in GEMDOS. The problem will manifest itself when the system has actually looked at more than 40 folders in one session (session=between power on and power off). So you can be safe even if there are many folders, as long as you power off before traversing 40 directory folders. This is known as the "Russian roulette" technique and is NOT recommended.

The auto boot program is still in test until we feel confident that it won't lead to other problems.

68K? K, who said K? Off the top of my head, these resistors are more likely
to be 68 OHMS. Any any case, wire-wound would be no advantage - ordinary
carbon composition or carbon-film is preferable for this sort of thing...

  I bought my 520 at Dillard's on sale for $695 (monochrome package).
In advertisements I haven't found much better. The 47th St. price of
$595 is the best I've seen yet.

The problem is further complicated by the need to keep file i/o as
genereic as possible so that it works on the max number of systems
and that tends to limit you to getc, putc, scanf, printf etc.
yeeechhh!!!! i tried buffering the i/o manually but the speed
advantage gained is lost in the access time for the floppy so all
the fancy (read hacked) code came out a wash. sorry

i doubt it severly, what is more likely is a port of system V with
a windowing system on top of it, there is a company that sells a
multi-processing OS for the ST but with no memory protection and
thats kinda like driving without a seatbelt.

On the subject of Avatex modems, I had the oppurtunity to try the 1200hc
modem. It is a far better modem in my estimation as it:
     1) Has a speaker
     2) Is Hayes compatible.

The one thing I noticed is that it seems slower than other modems. I also
have access to the Everex Evercom II internal 300/1200 baud modem, which seems
noticably faster than the external Avatex.

Can anyone confirm this? Is it possible to have two modems that are 1200 baud
operate at DIFFERENT speeds?

Is the answer to this going to be like 200 cps printers (most of which are
about 130-150 cps printers)?

Also, anyone tried the 2400-baud Leading Edge modem that sells here (on the
beach) for $289?

Hang loose,

Jonathan Spangler

Jim:

$495 for a 520ST is a heck of a bargain! I'm glad to know that at least one place is still offering the price.

Re: 1M - You can have your 520ST upgraded to 1Mbyte of memory for around $140 to $150 by several places. The upgrade appears to work fine if done carefully except that some power supply units don't work right with the added drain and require replacement of the power supply or a choke in series with it on the board. Professional upgrades usually involve changing the choke also.

Good luck. You can't go wrong for $495 and you can upgrade later.

Keywords: THUNDER! WTERM they work together

<<<<<>>>>>

To all those that are interested:
  I found out a few days ago when I down loaded WTERM by (I am so sorry, I have forgotten your name but you know who you are) and tried to use THUNDER! with it. Well they work together perfectly! I never thought that the solution to my problem would be in the form of a free program off the net - but I guess that's what makes the net so wonderful.
  WTERM's vt102 terminal emulation is oneof the best I have ever seen for the GEM interface. The Tektronix is a bit less than

perfect for Monochrome, as the lines at the top of the screen
are lost due to improper mapping. No problem, the Tektronix
emulator that I wrote does the emulation perfectly. By the way -
I will be posting BT (the nice Tek 4010, multi-graphics window,
interface to unix terminal emulator) as soon as I can get a
better scrolling routine worked out. Oh well...
  ANYWAY... I just wanted all to know that the facts are that
THUNDER! works well with WTERM (and WTERM is free). Thanks to all
that helped and even those that didn't.

                  Bob

For the Alcyon compiler, you have to change the calls on "fopen" that open
binary files to use "fopenb" instead. Thus, 'fopen(in, "rb")' becomes
'fopenb(in, "r")', etc. With that change, I was able to get them to work.

I downloaded the following from DELPHI tonight. Should be of
interest, and I'd REALLY like to get some comment from someone at
Atari.

8581 16-SEP 15:09 ST Programs
     New ST Products!
     From: MATRAT   To: ALL

According to Ron Robinson in St Louis:

Atari in London

--- News from the PCWS London ---

Atari announced the 2080ATF, an ST with 2meg of RAM, 4160ATF, with 4meg of RAM,
and the Blitter hardware. Kuma announced an expansion box to give the ST 15
MIPS (Million Instructions PER Second!) parallel computing performance. A VME
(Virtual Memory Expansion) box was demoed running several multiuser operating
systems. A storage OSCILLOSCOPE adapter box, weather satellite receiver,
several video digitizers, Pascal, Lisp, BCPL, and Fortran Compilers were also
shown.

Look Out APPLE, your //gs is in deep ..... well, you fill in the blank.

(I sent this to the net about a week ago, but never saw it come back, so
 it may have fallen into the bit bucket. In case it has, I'm resending it.
 Sorry if it DID go out and you've already seen it.)

I posted this on our internal Atari ST notes file. Since a lot of the info may be of general interest, I thought I'd include it here. Hope I haven't omitted anything of real significance.

Last nite I attended the meeting of the ST group of the Boston Computer Society (JBUG). There were about 40 in attendance, less than usual probably because some may not have realized the location is now MIT rather than BU. The following is a summary of my notes, so info may be lacking where I was distracted by literature being passed around, couldn't hear something clear, got bored, etc.

Allan Glick, the president(?), said the club would be putting on an Atarifest next sprint. He also wants reviews for the club JBUG newsletter.

VIP is going to $250. It is going to GEM on Sep 20, and those already owning it can get the upgrade for free.

TWIN, Atari's "Lotus" spreadsheet for the ST, will cost $99.

The final version of Joust is out (I saw it demoed - looks great!).

During the first part of the meeting, a TINYVIEW graphics demo was running, showing a bouncing ball reflected in several glass objects - the effect was startling.

A nice chess demo was shown - the product will be out Nov 1.

Degas Elite should be out in a few weeks.

No one had any info to offer on the release or availability of GDOS.

Tom Louzon(sp?) from Apex demoed a few of their products:

   Deep Space (from maker of Bratacus) appeared similar to the forthcoming version of Star Raiders from Atari. The graphics were really nice. You play with the mouse, keyboard, and joystick. It will be available in about 2 weeks for about $45.

   ST Karate was also shown, and looked arcade quality. Tom appeared to have a hard time manipulating his character and was quickly wiped out.

   Space Station, a game where you collect space crystals while navigating

about a space station, also appeared to have excellent graphics with nice panning scenery.

Next he showed a word processor that ran as a desk accessory. It appeared to be similar to 1stWord in function. Its main advantage was that it could be run while you were running another application which just happened to need some file edits.

First Mail also was briefly was shown. Its a mail merge program intended to be used with 1stWord.

Finally, he demoed Star Fleet 1 from Cygnus, another Star Trek like program (don't people ever get tired of blasting aliens?). The game featured an interesting twist on copy protection. It isn't copy protected, but in order to run it, you need to answer questions whose answers are scattered throughout the manual. Two BIG manuals come with it, so it would be quite a job to copy them. This may set a trend, but I wonder about the nuisance factor to the legal user.

Al Rizzo, the regional Atari rep, next got up and gave us some information he gathered from a phone call to Neil Harris at Atari:

- A CPM emulator is to go on the Atari BBS tomorrow or so

- We are about two months away from the new Atari 1200 baud modem

- The CPM hardware emulator will be demoed at the upcoming San Jose computer fair, Sep 20-21.

- Microsoft Write will be in beta test in October, and shipping in late Fall, for $130, from Atari.

- The "blitter" chip will be out in January. It needs a new set of ROM chips, and the package will be sold for $120

- ST versions of Millipede, Battlezone, and NeoChrome are still being developed (version 0.9 of NeoChrome was demoed during the meeting).

- ST Star Raiders is shipping this week

Erik Bryan demoed his TRUTIME clock module. It plugs into a ROM socket and the ROM plugs into it. Its lithium battery keeps the time for 10 years, and it comes with a program to set the ST clock upon bootup. This is the one Neil Harris of Atari likes and has commented on in USENET. It costs about $45 and comes with a 30 day guarantee. You can reach No Solder Required at (617) 547-2408. Its at 351 Massachusetts Ave., Cambridge, MA 02139.

Syntronics then spoke about the ST EZ Track MIDI software from Hybrid Arts. Its like a tape recorder that holds 20 tracks, and holds 40,000 on-off events. You enter your music via the MIDI keyboard. It has a GEM interface and looked pretty good.

After the formal part of the meeting ended, I saw Joust demoed and picked

up 7 new disks for our ABUG library.

/Don Peters, Digital, 617-689-1242/

Summary: ACTION *may* be coming for the ST but NOT from OSS

> I would love to see the reaction of some of you language experts to OSS's
> ACTION! for the Atari 8-bitters. It is structured, but reputedly so close to
> ....
> If we are REALLY lucky, maybe OSS will come out with an ACTION! compiler for
> the ST. Then maybe the DoD will select it to replace ADA!!!
>
> -John Sangster
> jhs@mitre-bedford.arpa

Finally! A subject *I* know about.... 8^)

ACTION! is owned by ACTION COMPUTER Services, not OSS. OSS merely has the 8 bit rights to sell ACTION!. Clint Parker, the author of ACTION!, is working with Quantum MicroSystems Inc. of Syracuse NY now (under contract?) from his home in Delaware. If I understand the owner of QMI (John DeMar), Clint *MAY* be working on ACTION! for the ST. However it's not even close to being finished and the original will be extended to dispell some short comings of the original language.

Personally I think, this late in the game ACTION! may have missed any 'window of opportunity' it might have had.

The first paragraph is basically correct as I met with Mr. DeMar only a couple of weeks ago and my brother is presently writing for QMI. The second is pure conjecture on my part.

If you are having problems with the DRI malloc, first call sbrk at the
beginning of your program. Call it with an argument equal to the total
number of bytes you anticipate needing. It allocates space to the heap
where the dynamic memory management is done. See also brk. Both
are documented under brk in the DRI C manual.

1st Word is up to version 1.06. The new version will either single or
double space, and there also corrections for bugs in prior versions.

To receive the update, send $9.95 plus $2.50 for shipping and handling to:

Atari Customer Relations
PO Box 61657
San Jose, CA 94088
Attn: 1st Word

You MUST send your ORIGINAL 1st Word disk to receive the update, which
includes a disk and a manual.

PS: I will update the signature for the correct address, but do use:

I thought the LQ printers were compatible with older 9-pin printers!
Of course the 24 or 28 pin printers are capable of much higher resolution,
but the screen pixels are the resolution limit in a screen dump.

(I havn't tried one on an ST but I have tried MX80 graphics-printing
software on an Apple II with an LQ1500 and it worked fine.)

My vision of the near future, though, is nice fonts printed from ST software
on both 24-pin and laser printers. Any GDOS wizards out there working
on it? (Well, they wouldn't tell us yet, would they?)

Maybe I found a reason for some system crashs.
GEMDOS uses a 3000 word memory area starting at 0x29dc for system purposes
(memory descriptors, root process descriptor, directory entries, ...).
Memory of this area is allocated in blocks sized in multiples of 8 words.
Released blocks are collected in free lists for each blocksize.
Now it comes:

A block once created with a particular size has this size forever !!!!
I could'nt find any routine to split or combine blocks.
The blocks for directory entries and memory descriptors differ in size.
If your first program after boot extensively uses Malloc() and Mfree() the system memory will be fragmented into 8 word blocks (actually 9 words because of 1 additional word for blocksize information). After that any request for blocks of other size will fail.

I have no idea, why system memory is limited to such a small area, nor why this management scheme is used.
Any comments on that ?

Summary: Demand for "BASIC-like" languages?

[]

I have a feeling that there are some people out there who are afraid of C or hate edit-compile-link cycles or whatever, use their computer for word-processing and such and keep waiting for a programming language they feel like using. (ST-BASIC doesn't count as a language as far as I'm concerned, and LOGO may be too wierd for many.) I don't know anything about ACTION, but if it is not too low-level maybe it DOES have a market!
I posted a while ago that HBASIC, an incrementally compiled BASIC-like language for the ST, is about to come out (beta test version supposedly out now but I havn't got one yet). Its emphasis is on SPEED (including

floating-point) and on access to assembly.

If there are people reading this and longing for an "easy" language
or interactive (but not reverse Polish) environment, let us hear!
(Personally I'll stick to C for now, thanks to the 15 sec compile-and-
link time with Megamax on a RAM disk - just wish they'd fix those bugs...)

On the other hand, it is normal for a person filing a patent application
to make as broad a claim as he thinks reasonable. The are a number of
highly irritating patents covering things like mice, pull down windows,
and character generator ROM's. If you read the patent applications, you
immediately say 'this guy has got to be kidding', but unfortunatly, they
are for real.

It is up to a manufacturer to make sure that they do not use ideas that

are patented. If Sun chooses to enforce their patent, they could cause
a small operation a lot of pain. The patent may not seem reaonable, but
it was granted, and until someone invests the neccessary legal time and
money to contest it, it is legally enforcable.

When I tried to print out the proff manual, I discovered the my
printer did bizarre things with underline and boldface. (underline
came out like 't_h_e_' and boldface became 'tthhee'. I realized
that my printer did not recognize the backspace commands. (which
is alright cuz it isn't meant to in logic seek mode.)
   So, I said 'No problem, I'll just load in the printer driver
from my START disk.' Discovery number 2: The driver in START
only replaces the screen dump utility, not the regular driver.
   So, I said 'No problem, I'll just load in a driver from my
First Word disk'. There isn't one for a Prowriter and no info on
how to make one.

  Any body have any spare Prowriter drivers lying around, or any kind
of information that I could use to make my own???

Hi,
    I know someone who is very interested in purchasing a 520ST, but he
wants it with PAL video output instead of NTSC because he is planning to
take it with him to England. Is there any way to get an ST in the USA
with PAL?
    thanks,
       Mike Cohan

I'm afraid the "general idea" concept is no bar to a patent! Many years

ago, Western Electric (I think. . .) obtained a patent protecting their interests in NPN-to-PNP transistor connections! Not too long after both varieties of transistor were circulating in their lab, someone saw that the collector of one type could be connected to the base of the other type (you can't do that with tubes!). Pretty general idea, eh? My employer paid royalties on this invention until the patent expired.

As another example, there has been a long battle over who first invented the laser. Recently (the last year or so), a winner was declared and a number of patents issued. Can you think of a more general idea than the laser?

Whether or not Andy's invention ultimately proves patentable (because of details having to do with the dates of the first public announcement and filing of the patent disclosure, prior art, and so forth), the idea is quite clearly patentable! Further, if the claims are drawn up broadly (lawyers are hired for this purpose. . .), the patent should cover any realization of the idea as used in memory mapping systems. Remember, though, that the patent could be invalidated merely by proving prior art! (Does anyone have an example of an equivalent, but earlier, implementation of this idea? To invalidate the patent, the prior art would probably have to involve dynamic RAMs. . .)

A patent does not just "protect the inventor of a process from those who would use his work as their own." The idea is protected in all realizations that are covered by the claims made in the patent, as long as there is no reason (such as prior art) that they should be invalidated. For a period of seventeen years, the inventor is allowed to control the use of his invention, and charge for the privilege. In return, he makes the invention public and relinquishes all control of the invention at the end of the patent's lifetime.

If there were no patents, the only protection people would have is to keep everything secret (so-called "trade secrets"). This would impede the flow of information much more than not being able to use an invention without compensation to the inventor!

I use three different terminal programs to connect to bulletin boards
and two different VAX computers. I have been experiencing problems
with my terminal locking up on one of these VAXES. The lockup always
occurs at the same place in the login procedure and happens when using
the uniterm (v1.2) program or the VT52 emulator accesory. The only
program that avoids this lockup is STTALK. After the serial line
locks up, neither the emulator.acc nor uniterm will communicate with
it any more. However, STTALK will work even after the other programs
have locked the line, without hitting the reset button. The other two
programs will no longer communicate with the serial line without a
reset.

The problem with STTALK is that it eats up the screen (I lose four
lines) and it does not support KERMIT (of course neither does
uniterm).

There certainly should be a LOT of demand for it. You ought to bring that to the attention of Addison-Wesley Publishing, which I believe is the marketing agent for it. They are located in Reading, MA and their phone number is (617) 944-3700. Point out the cost of the 520ST and how many have been sold so far. (Neil???) I think it is well over a quarter million units. Many of them to students and computer scientists interested in publishing technical papers.

The only point of contact I know at A-W is Keith Wollman, who is at another office, (617) 246-5100. He is an "Acquisition Editor" for undergraduate computer science texts. He may well know Knuth and be interested in the TeX product.

-John Sangster
jhs@mitre-bedford.arpa

P.S. - If YOU are interested in porting TeX to the ST, A-W probably would supply the ST!

Summary: Receiving OS-9 68K for Atari ST Monday

I just heard from Customs in Windsor and I'll be receiving my OS-9 port for the Atari ST on Monday or Tuesday (most likely Monday).

I have heard already from other OS-9 users who report that it seems to be very fast for Floppy Disk access. I'll say more later when it arrives.

Cheers! -- Jim O.

>money to contest it, it is legally enforcable.

I believe that the patent law allows a special challenge that costs only
$1500. This is something fairly recent, but I believe anyone can do it
with enough proof and then the Patent office takes over.

ATARI CORP. PRESS RELEASE, Sept. 18, 1986

(Sunnyvale, CA) Atari Corporation announced today that it has filed a Registration Statement with the Securities and Exchange Commission for an initial public offering by the Company of 4,500,000 shares of Common Stock (and up to an additional 675,000 shares that may be purchased by the Underwriters from the Company to cover over-allotments) through an Underwriting group to be managed by PaineWebber, Incorporated. The price range is anticipated to be between $11.50 and $13.50 per share, and the offering is scheduled for mid- to late October. A written prospectus with respect to the offering will be available from PaineWebber, Incorporated.

Atari Corporation develops, manufactures, and markets microcomputer systems and software as well as video game systems, designed to offer advanced technology at low prices. The Company's product line consists of the 16/32-bit ST computers, the 8-bit XE computers, and the 2600 and 7800 video game systems, with associated software and accessories.

A registration statement relating to these securities has been filed with the Securities and Exchange Commission but has not yet become effective. These securities may not be sold, nor may offers to buy be accepted prior to the time the registration statement becomes effective. This (communication) shall not constitute an offer to sell or the solicitation of an offer to buy nor shall there be any sale of these securities in any State in which such offer, solicitation or sale would be unlawful prior to registration or qualification under securities laws of any such State.

For more information, please contact Greg Pratt, Chief Financial Officer of Atari Corp. at (408) 745-2349.

I use uEmacs on the ST for everything (v3.7). I hacked on version 27 for a year with CP/M-68. And I use GNU_EMACS on a VAX. While the commands are similar between the two programs, GNU is chock-full-o usefull features that the current micro version just can't handle. But from looking at some of the GNU sources I would say "if you want to port it without Mock Lisp, forget it." Mock Lisp is an integral part of the package. In fact many of the mode specific and "extra" features of the GNU program seem to depend on Mock Lisp.

I suggest if anyone wants GNU on an Atari, she check out the program carefully and the sources; then compare those to uEmacs and its sources with the goal of expanding the micro version to include some of the features. But just think how fast your disk space will dissappear with 100K info files lying around, and how will you handle all those real un*x functions that rely on concurrency?

One idea I had, but which seems beyond me now, is to merge uEmacs with Xlisp. With a bit of tweeking, the Xlisp interpreter can be made to read and evaluate mock-lisp files. BTW a new version of GNU has been announced and might be out by the time you read this.

How about calling your accessories xxx.ac2, so they won't boot, and have ONE
accessory that lets you install those by name. That way you can install
them one by one as the session proceeds and you know what you actually
need, and you never have to deal with the problem of reclaiming memory!

In a nutshell, GNUemacs is much more robust than uEmacs is.
In GNUemacs, you can write your own functions and rework every
command and function to your taste without modifying the actual
editor.

GNUemacs also has a wonderful C editing mode which essentially
formats your code for you, keeps track of braces and parentheses
(how many times have you had a program fail because you left out
a brace or parenthesis?), allows you to compile the program from
within the editor, and if the compile fails, will place the cursor
at the point of the first bug in your program. (Phwew! LOVE those
run-on sentences!)

'Nuff said?

Xref: mnetor net.micro.68k:1254 net.micro.amiga:4823 net.micro.atari16:2093
net.micro.mac:7176

In the September 18, 1986 issue of Electronic Design magazine, there is an
article on page 27 describing the new microprocessor from Motorola, the 68030.
The chip is said to run software 20% to 30% faster than the 68020. The chip
is supposed to be available in mid-1987, along with an improved math
coprocessor, the 68882, which will be up to 25% faster than the 68881.

Oh yeah, by the way, the chip will have a built-in, paged memory-management
unit (in case anybody cares :-)). The MMU is a subset of the 68551 PMMU.

The chips have several other interesting features, which I will leave to the article, so that I won't be accused of plagaurism (sp?).

The bus data transfer rate of the 68030 is 40 Mbytes/sec.

Hopefully, now we won't have to put up with the Intel fans (short for fanatics? :-)) telling us that Intel has the best microprocessor.

Now, when will I be able to connect one to my Amiga?

Rodney Ricks,

A few people have mentioned Mock Lisp in GNU Emacs. I'd like to correct this: Mock Lisp simple Lisp-like language used in Gosling Emacs which is now sold by Unipress Corp. It is called "Mock" Lisp because among other things it doesn't have a CONS function. GNU Emacs Lisp is a real Lisp (including CONS) which some pretty substantial programs have been written in. Most of GNU Emacs's editing commands are written in Lisp.

In my opinion, trying to merge Xlisp with MicroEmacs would result in a horrible kludge and trying to make it able to run GNU Emacs Lisp functions would, if it is feasible at all, give you a program as big as GNU Emacs. It would be simpler to just port GNU Emacs to the ST. This is not a completely crazy thing to contemplate doing on a 1 megabyte machine and

is a completely reasonable idea with 2 or 4 megabytes. (The program text segment of GNU Emacs is about 600k on a VAX, which includes a lot of sharable Lisp code as well as a lot of code for things like Unix asynchronous process control which would have to be flushed on an ST).

Someone (Bradley Mitchell?) has made an extensible MicroEmacs by combining it with a FORTH system. That seems like a more sensible approach than writing a Lisp system if the goal is to keep the program small; however, writing very complicated macros is probably more difficult. I've never used FORTH so I don't know for sure.

I am very impressed with the latest version of Emacs that has been posted.

A few comments:
  -if you hit F10 you just exit, no questions asked. I find this a little scary.
  -When run in colour mode, I only have a colour tv, so it is not worth using, the characters are difficult to read. So, I am using the Hi50 program in monochrome. I would love to modify Emacs 3.7 to use all 50 lines on the screen. Source would be nice...
  -I opened my monitor and expanded the vertical resolution. Definately a very good idea. 50 lines was pretty scrunched before, and now it seems almost as legible as 25 line mode. (Yes, circle generated by graphics programs are a little too tall, but I am not complaining... as an aside, can I expand the horizontal size too??? I didn't see any obvious way to do it.

Thanks

-=-=-=

them resident so one could use them anytime.

Could these be done? You bet, and they would be far more useful than unloading an acc. All it takes is an enterprising individual. And if one isn't out there, then wait, I'll get to it after my current project (read in a year or so).

Mike

Yea raHHHHH!!!!!

Action would be a welcome addition to any programming environment. The language is similar to C (yet limited on the 8bit version) but lacks the awkwardness of C syntax, and is very structured.

I could not say enough about Action! if it were implemented to allow as much flexibility as C. It would be my #1 choice, although I like C a lot. Clint Parker who developed Action! knows exactly how to write an excellent programming environment. And if it were on cartridge to boot!!! Look out!!

Our experience has been that the best way to use the harddisk for compiling is:
1. partitioning it into 4 partitions first.
   This way creating files takes not too much time.
2. using a ramdisk for every temporary file. This speeds up a lot !

However, the whole slowness of the GEMDOS filesystem handling is a pain
in the *** ! Maybe the following would help:
Implement a track buffer for reading. Useful for floppies only, I think.
But it would help considerably.
Do some write-behind if possible. It gets a bit complicated, and I don't
know if it would fit into the bios well.
!! Beat those bugs out of GEMDOS !!
The slowness of file creation is a real bug. As far as I know the file
system layout, it should not depend on the filling grade of the partition.
When you watch the activity light on the harddisk during file creation
you see that there is something realy weird going on.

There is a chkdsk available for the ST's and it is called precisly that-
'CHKDSK.TTP'. I Dl'ed from compuserve. It is probably on othher BBS's too.

Keywords: SH204 HARDDISK

We recently aquired the European SH204. Since we found several problems
with the previous prototype harddisk, we were eager to compare them :

- The noise level seems to be down by a factor of two (subjective).
  Where the prototype produced a steady hum, the commercial SH204
  produces mostly fan-noise, which to us is much less distracting.

- The cablelength is now 60 cm, which allows placing the drive next
  to the ST with the indicator light facing towards you.

- Partitioning of up to 4 partitions (max. 16 M per partition) is now
  possible.

- The major problem with the prototype is the slow speed of writing on
  a substantantially filled hard disk. This problem appears NOT solved
  in the commercial SH204.
  The measurements below show that overhead on file writing depends
  on the usage of a partition. For a partition containing 7.5 MByte,
  allocation for an empty file takes approx. 7 seconds ! (on a floppy,
  this takes 4 seconds.....)

  Copying time for 4 folders totalling 55 items (1.5 MByte)
  from harddisk into another partition (of size 10M) :
    destination partition empty   : 2:06 minutes
    destination 1.5 M filled   : 3:27
    destination 3.0 M filled   : 4:38
    destination 4.5 M filled   : 5:52
    destination 6.0 M filled   : 7:03
  With the partition containing 7.5 M, writing an empty file takes
  approx 7 seconds and a 32kByte file 7.5 seconds. Writing the same
  file on floppy takes 10.5 seconds.

The above measurements were done using a AHDI.PRG version 1.4 (dyer).

As long as this problem is not fixed, you should consider if this is
a device you want :

  File reading and program loading is fast.
  Applications allocating many small files (compilers...) run slow,
  sometimes slower than a floppy drive.

I have heard from a "usually reliable source" -- one with fairly good sources
inside Atari -- that the information in that show is probably about 2 years
out of date. Atari has for a couple of years had only around 1000 employees,
and they have NOT recently laid off 6000 of that 1000.

Ok, I have a question for the net. I've just got in my copy of OS/9
for the Atari. It seems to be a fairly complete operating system
and everything works. I will post a short review in the next week or
so. But, OS/9 is not a small system. The directory runs to four
pages and this is sans languages. In short, it's time to buy a

hard disk. This particular port of OS/9 supports disk made by
two companies, Atari & Supra. So sports fans, which do you think
is the better disk? Please mail or post replies. Of course, in a week
or two, I will summarize to the net.

Richard Piner
piner@galileo.UUCP
(was piner@pur-phy.UUCP)

BTW, the hard disk implimentation is a little strange. It seems that
a small portion of the disk must be left for GEM. The partition can
be very small, but it has to be there in order to boot the system.
I thought the industry learned not to use ROM when Radio Shack stopped
making the Model III. Oh, well.

Keywords: BASIC EOF BUG
Summary: Is there any use for EOF()-function?

Am I missing something, or is the ST-BASIC EOF function totally useless?

I tried to read a file upto the end and I wanted to detect eof by means of the
eof function. If I don't include the "on error" statement I get a "You reached
end-of-file" error at line 170, but if I do include the "on error" statement,
then I end up in an infinite loop.

Here is my ST BASIC program:

```
100   on error goto 210
110   line%=0
120   open "I",#1,"file.ext"
130   line input #1,buf$
140   while not eof(1)
```

```
150       line%=line%+1
160       print line%,buf$
170       line input #1,buf$
180   wend
190   close #1
200   end
210   print "Error";err;"at line";erl        <--- just to see what is going on
220   resume next
```

Re: an earlier posting about why Gnu *probably* wouldn't work on an ST.

What I was really trying to say was GNU_EMACS needs the Lisp functions to remain such a wonderful package. I was responding to a question about when someone was planning to port GNU, without lisp, to the ST. I don't think that port would be worth it. It would be a step backwards for GNU. As for porting it to the ST. My 1040 only has about 896K left when it loads without DAs. Sounds like a lot doesn't it? Try loading a 600k application, up to 100K of source files, and then expect the ST to let you compile and link those modules without exiting. The linker can run in 128K, but with large compilations it needs 256K. Let's see 896 - 600 - 256 = 40. Given the problems with malloc and free on the ST, that 40K is gone in no time.

BTW I have been using uEmacs 37 which includes a Cmode, a non-braindamaged word wrap and fill (i.e. it understands that a word includes punctuation marks when it wraps and that sentences are terminated with two spaces when it fills). This version also supports the store macro function which allows you to write routines that are a little more useful than the record keyboard macro can be but still no conditionals or loops.

Now for the other side. Unipress has a Gosling EMACS that works on an IBM-PC (full memory I believe) and needs a hard drive. But like someone said, it doesn't support the full lisp that GNU has. And I use that lisp code and Info for my students who write essays with GNU_EMACS. Perhaps with some anti-C maneuvering (overlays on the hard drive), GNU_EMACS could be ported complete with "peaches en regalia" (F.Z.). *8^}

Summary: When??

In article <8609201633.AA06324@ucbvax.Berkeley.EDU> "V5130B::MENTON"
<menton@v5130b.decnet> writes:
>Did I hear right, on the cable TV show "Computer Chronicles" on 9/20/86?
>Atari is laying off people, down from 7,000 not long ago, to 1,000 in the
>near future? Because they LOST $500 million (!) last year ??
>   Bob Menton
>   MENTON@NRL-ACOUSTICS

These numbers do sound familiar. They sound like what occurred when Mr.
Tramael took over ATARI from Warner. When he took over, there were about
7000, many of them in marketing. Within a few months, there were only a
hand full of marketing people, a core engineering staff (mostly working on
the ST), and the manufacturing facilities were all put under automation.

Atari did lose $500 million the year it was sold to Mr. T., in fact that
was one of it's better years. Since the sale, Atari has not only been

doing well in the sales, but it may be showing a profit for the first time since the release of the 800.

Is it possible that this show was a repeat?

Ironically, Atari has been one of the few PC companies that has shown improvement this year (1986). Even grand old IBM has been feeling the Atari bite of the market.

Just out of curiosity, what is the ticker symbol for Atari? It used to be part of Warner Communications, but appears to be a separate company now?

It's fairly hard to reconcile the rumours of Atari's financial problems with their announcement that they are going public. One goes public to attract capital, which might suggest that they're cash-short, but it's rather hard to find investors who would propose to sink money into a company on the verge of going down the drain.

Since financial information on Atari is hard to obtain, it's hard to know what's going on without looking at the prospectus. However, I suspect that the accounts I've seen in places like INFOWORLD and BYTE are more likely than most: Atari has been selling all the ST's they can make, but they can't make enough. In that light, an IPO seems reasonable, in that it might help them to afford more production equipment, warehousing, and inventory.

Preliminary remark: my own 1040 has the UK keyboard, but various other
keyboards exist around Europe. Usually, they allow the extra accented
characters by use of the alternate key. Of course, the normal keys are
moved around (QWERZY, AZERTY, etc.). My own word processing needs are
mainly english, but sometimes I need german or french. 1st word will deal
with this, but in a clumsy way.
Question, therefore. Are there keyboard reconfiguration programs which
allow not only changing keys, but also adding them via the alternate key
(my own has no reaction to use of this key). Of course, any reconfiguration
should be compatible with whatever word processing package I decide to
use, and I don't know yet which that will be.
A biento<backspace>^t.

I am pretty sure that this was old data. Atari layed off many of their workers when they were owned by Warner. This was due to shifting much of the production of their video games to offshore facilities. I haven't heard of any layoffs since Jack has owned the company.

I read somewhere that the 13 pin video connectors for the ST are now available from ATARI as spare parts. Does anyone have a part number so I can order a few??

Hello,

For Bitnetters it is extremly difficult to get files from
the arpanet. I recently discovered that on the fileserver
SILMARIL@FINHUTC.BITNET someone is collecting public domain
software for the ATARI-ST. However, the collection is not
growing very fast, probably because almost no one knows it exists.
So, whoever has public domain software for the ST and knows how
to transfer files on BITNET, please send it to LK-ET@FINHUTC.

By the way, what is left of the initiativ of what's his name
to setup a "net.atari16.sources" and how can I benefit of
this?

Greetings, Berend F. de Vries.

> How the hell can the patent office grant patents like this? ...
> ... the idea is too obvious.

The patent office is not omniscient, and the idea certainly wasn't as
widely known five years ago as it is today. It's fairly likely that
somebody *somewhere* had the idea earlier, and can prove it -- for
example, I'm fairly sure at least one blurb for some early MMU chip
mentioned the notion -- but it's asking a bit much to expect the Patent
Office to know this.

Ignoring for the moment the question of whether Andy's then-current
employer has some say in the matter, what will happen is that Andy will
be able to go out and ask assorted competitors for royalties. There's
a fair chance that most of them will pay rather than fight, if he's
reasonable about amounts. If he's not, or if somebody decides to balk,
there will be a court battle, which Andy probably will lose. The idea
is too simple; my guess would be that a vigorous literature search will
turn up either prior publication of the idea or something close enough
to make the final step "obvious to one skilled in the art", either of
which invalidates the patent. In recent years, as I recall, most court
challenges to patents have succeeded: it's too hard to come up with
something that is really and totally new. Andy's best tactic would be
to ask for a modest royalty that's not worth fighting. The chances of
successfully gouging someone for a "WHOLE lot" of money aren't good
unless he deliberately picks an ailing victim who can't afford a fight.

>If it's so obvious, why didn't anyone think of it before Andy did?

I did; it's the obvious way of building an MMU that doesn't introduce extra
wait states, and applies to the 68K family because the other common
16/32 bit CPUs don't require custom MMUs.

>Is the Set-UID bit (also patented) any less obvious? Not to me,

HI THERE IN COMPUTERLAND,

I WAS WONDERING IF SOMEBODY HAS A (C-) SOURCE OF LEX AND/OR YACC.
LEX AND YACC ARE TWO UNIX UTILITIES TO GENERATE LEXICAL
ANALYZERS AND SIMPLE AUTOMATONS. I EVEN WOULD BE VERY GRATEFULL
IF SOMEBODY COULD TELL ME HOW TO PRODUCE A NEW LEX WITH A LEX
(I HAVE ACCESS TOO A WORKING LEX IN A UNIX SYSTEM).

>If it was developed with Federal money, then policy says that there
>will be no fees for use of the patent. If Sun owns it, then there
>probably will be fees.
>
>--

The problem is that the idea IS old... Many companies have used
the idea for paged MMU's. The idea would be obvious to people who design
high speed memory systems. High speed memory that uses RAS/MULTIPLE CAS
to cut down on access. When you think of one event followed by another
you *try* to do things in parallel while waiting. The question
and point I am making is two fold (OLD IDEA) and OBVIOUS) *in the circles
of memory design*. I'm really worried more about the *general case* of having
our common thinking patented. Or THEFT of ideas that are in current use
for profit. Some simple ideas don't have patents for similar reasons that
not all people use locks. Here the theif can make you pay... The later
comment should in no way be implied with SUN, it is an echo of general
concern that effects many of us. If someone comes up with something *new*
and our knowledge is extended then great, give a patent!

I would like to say that I understand Sun uses the method of RAS/CAS
delay decode. Perhaps they were the *first* and had the idea shortly after
DRAM's came out. Then my idea of OLD would be out..... > 10 years.
In any case I am quite interested in why they think they can get a patent.
Because if such simple ideas can be patented then it would be a good education

for all of us.

Mike Gore
Institute for Computer Research.
These ideas/concepts *do not* imply views held by the University of Waterloo.

I think ANSIGRAF by Grafikon Ltd. is the program for you.
It emulates a VT102 and also does a really good job of
emulating a Tektronix 4014. It uses GEM, so THUNDER should
work although I haven't tried that combination. You might
want to find a store that sells it, bring in you copy
of THUNDER and ask to try it out.

Keywords: games for ST

I have ported LARN version 12.0 to the ST and am ready to distribute it.
Because the .ttp file is 170K plus another 30K or so for support files, I
am going to avoid posting it to the net (however, if someone else wants to
risk the wrath of irate administrators and people who don't have uudecode,
compress, sq, or whatever, I won't object). So, here is how I'll handle
it. Send me a disk and return address and I'll copy it for you. If you
want the sources (compiles under Lattice C) send another disk (or if you
have a double sided drive and I can convince my office partner to copy
it, a double sided disk will hold both the compiled and source files).

LARN is an adventure game (much like HACK, but different). It easily
fits in a 512K ST with one single sided drive. Since it doesn't create
intermediate files (like HACK), one doesn't need a RAMdisk or anything
special to play.

I also have HACK and can distribute it, but have not done any changes
for several months.

Until I ported uuencode/uudecode (about a month ago), every
uuencoded program I got from the net was successfully downloaded
to my ST in 8-bit "image" mode after having been decoded on our
VAX (old) or Pyramid (new). People having problems with uuencoded
files can probably blame non-UN*X sites for munging the files somewhere
along the way. As far as blaming your color monitor for trashing uE3.7,
you can forget it - I've been using it with both monochrome and color
monitors for several weeks now. By the way, the color version looks great!
My only complaint about uE3.7 is the SSLLOOWW disk access time (blame it
on "gemdog" ;-).

A couple more questions....

Recent reviews have mentioned that 1ST_WORD limits you to only single spaced documents. Is there a work around for this, other than by adjusting stuff on the printer? Also, rumor (around here, anyway) has it that Atari is about to ***raise*** its prices on the ST. Has anyone else heard the same? (I don't imagine Neil@Atari can comment on this one).

thanks for any replies.

WRONG!

GST owns First Word. Atari has (had) distribution rights to it and paid GST for every copy that went out with a system and every copy that a dealer gave away (every one with a label on it, anyway). It is *NOT* in the public domain. Notice the copyright notices on it and on the documentation when you print it. Neil Harris (Atari Marketing type) just

spoke at our user's group meeting last Monday and discussed this issue,
so this information is straight from the horse's mouth (so to speak -
no offense, Neil). If you have further doubts, call Atari. Better
yet, call GST, that'll cost more.

Any idea of when he patented this? This is a very common idea, doesn't
sound like something you could patent.

Keywords: RCS Resource MWC

I just got Mark Williams C (for $139, BTW, from San Jose Computer),
which is a real complete package for the price: it includes uemacs,
make, ushell, an assembler, and a slow-but-seems-ok c compiler.
But it doesn't include a Resource Construction Set.

Does anyone know if an RCS (source or object) exists in the public
domain, or if it is available for sale separate from the Developers' Kit?

Thanks in advance.

bridge, VA, the basic 520ST, monochrome monitor, one SS disk drive is going for $549. This is the same system that sold for $495 (on sale) not long ago. I didn't think that dealers would raise the 'sale' price. This (and any further possible price increases) could be a set-up for a big price CUT several weeks before Christmas. Or, has supply and demand worked its magic? Can the ST be selling **THAT** well ??

>

> If it's so obvious, why didn't anyone think of it before Andy did?

Let's look at this for a minute. You have the following problem:

) you want virtual to physical address mapping
) standard practice is to map only the high order bits
    (this predates Andy by a good long time)
) virtual to physical mapping takes some time
) you want to use dynamic rams
) dynamic rams require half of the address, and then, some
    delay later, the other half
) Gee, Wally, what do we do now?

It's not that nobody thought of it before, but nobody patented it.
It's not a clever idea; it's the only reasonable solution.
I had a design like this for the 6809 and dynamic memory before the
68000 even came out; I just never built it.

It bothers me that such ideas can be patentable. When you design
a new machine, these patents can restrict your design space; if they
start patenting all the good solutions to common problems, what do
we have left to design with?

Summary: How to copy PC/Intercom

PC/Intercom does an excellent job in emulating a VT102 type terminal.
I received PC/Intercom on a single sided floppy disk. However I want to move
it to a different double sided floppy, where I keep all my utility programs.
Copying the files seems to be successful, but if you double click on the new
file, PC/Intercom insist you insert the original disk. The same holds even
if you only disk-to-disk copy to a new single sided floppy.

The question: How do you get round the copy protection?
              ======================================

(After all, the copy protection is not completely effective, because I can
make a disk-to-disk copy using a tool called SUPRCOPY)

   The Sun patent is only valid until it holds up in a patent
court. I believe that it can be argued on any of several fronts.
One is that it is obvious using the existing technology of the
times, which is grounds for not granting (or voiding) patents.
THe other would be that it was done and documented prior to the
patent. Personally, I have documentation that it was discussed
here at Fortune five years ago, and I haven't even tried to
look any harder than that. Does anyone know when the patent

disclosure was filed for the Sun MMU patent?

    Aw well, I knew I should have filed for those ideas I had,
using PALs to decode address spaces, using ROMs as clocked state
machines, using memory to store information in.....

I couldn't find one either, it being some kind of non-standard.
I did however manage to kludge up an adapter to a .1" centers edge connector by
sticking copper tape on an appropriatly trimmed piece of pc board using the
cartridge artwork included with developers kit as a guide. It's ugly but it
worked like a dream.
If your not in the hurry I was I suggest you draw up and etch your own.

No more tears out there in NETLAND for all those inaccessible uuencoded programs. I have written a version of UUDECODE in ST BASIC. The program is included below.

How to use -- Simply run this like any other BASIC program. It will prompt for the input file name (the uuencoded file), and the output file name.

I have successfully decoded three programs (four files) on my ATARI 1040ST using this program, including UNITERM and microEMACS, which were posted on this BBS. I haven't had any failures yet.

Caveats:

1. I had to work around several ST BASIC bugs, some of which are mentioned in the comments to the program. This means that if ST BASIC is updated, or if the bugs are somehow specific to my system, you may have to edit this program to get it to work.

2. The output file name must be specified by the user at the appropriate point. This is unlike "standard" UUDECODE, where the output file name is read from the "begin..." line of the input filename. This is due to problems with the BASIC statement LINE INPUT #. These problems only seem to occur after opening a file.

3. The first line of the UUENCODED file should be the "begin..." line. This first line is ignored. Encoded binary is assumed to begin on the second line. (Also not standard UUDECODE, and also due to the LINE INPUT # bugs.)

4. If your UUENCODED file does not contain exactly 45 encoded bytes per line, then this program will not operate correctly as is. There is no problem here if every line in your encoded file begins with M. Only special case: last line of encoded binary can begin with any character between ! and M (refer to an ascii table). (While this is not "standard", I have run across no

exceptions as yet.)

5. The program assumes it has completed if it reads in a line
   -- which reads "end"; or
   -- which begins with a space; or
   -- which is blank.
   (Only the first of these is standard, but as before, I haven't found any problems yet.)

Despite the caveats, I have not had any trouble UUDECODING anything yet.

(But, I regret that I cannot assume legal responsibility for any losses incurred by the user.)

As far as I know, UUDECODE is public domain. Presumeably, then, this program is also. (Could I really find anyone who'd pay for ThiS?)

GOOD LUCK! and let me know how things turn out.

**********ACKNOWLEDGEMENTS**********

I have to thank John Sangster (jhs@mitre-bedford.ARPA) for providing me with the functional specs of UUDECODE.

**********STANDARD DISCLAIMERS, ETC.**********

If this program fails to operate as specified, return for a full refund.

As with any test(y) program, please exercise appropriate caution in the use of this decode program. In particular, I suggest that if the disk you are using contains the only copy of anything important, you aren't using appropriate caution.

Princeton University bears no responsibility for any part of this bulletin. (Is it legal for me to say the same for me?)

Yes, there's something called "memory fragmentation". There shouldn't

in principle be any difficulty in zapping an accessory, but what is the point except to recover the memory it was occupying? But that memory is a little block somewhere that is most likely not contiguous with the rest of free memory since there are likely other desk accessories in the way. To make effective use of that memory, you either need address mapping hardware (which the ST does not have) or you need a memory allocation strategy that is able to make use of fragmented memory or you need a way to move active processes so that you can coalesce the unused blocks of memory. Moving processes is dangerous, for they might have a copy of their own or other processes' base page address tucked away in storage somewhere. One MIGHT be able to get DOS to know about the block of memory freed up by a removed desk accessory so that at least Malloc could use it, but that probably would not help most programs. Your best bet would be to load another smaller desk accessory into the same slot.

The next two I am sending are:

1. SPELL.DOC - User's Guide for SPELL.PRG - A spelling checking program that
               I have written
2. SPELL.PAS - OSS Personal Pascal source code for SPELL.PRG

I regret that I am presently unable to send the uuencoded executable code.

SPELL 1.0 User's Guide

HOW TO USE THE SPELL PROGRAM:

SPELL is a program that allows you to detect and correct spelling mistakes in disk files. SPELL should work with files produced by just about any word processor. SPELL has been tested on files produced by the 1ST WORD word processor.

THE WORD LIST:

SPELL uses a disk file named "words.txt". This file contains all words that SPELL recognizes as being correctly spelled. When you start using SPELL, this file will be empty, and SPELL will wonder if every word in your document is misspelled. As you check the spelling of more and more files, SPELL will know about more and more words. Eventually SPELL will have a dictionary containing most of the words that you use, and will only ask you if misspelled and unfamiliar words are misspelled.

RUNNING THE PROGRAM:

When the program is first run, the file "words.txt" is created on the default disk. Make sure that SPELL has write access to the disk on which SPELL is stored.

Then all words stored in the file "words.txt" are loaded into memory. If SPELL is being run for the first time, no words will be loaded.

Now you are asked for the name of the file for which the spelling is to be

corrected. Enter the filename that you want checked. SPELL must have write access to this file.

After the file to be spelled is specified, whenever SPELL encounters a word that is not in the file words.txt, you may:

  (1) correct the spelling of the word
  (2) add the word to the dictionary

To correct the spelling of the word, type in the word as you would like it to appear in the document being checked.

If the word is correctly spelled, or if you've just corrected it, then you may want to insert it into the dictionary. To add the word to the dictionary, place the mouse in the appropriate box and press the left mouse button. When you add a word to the dictionary, whenever SPELL sees that word again, it will know that it is correctly spelled, and will not ask you about it.

UPDATING THE DICTIONARY:

Why do you need to update the dictionary? Well, every time you start the program, the dictionary contains all the words that were in the file "words.txt". As you insert new words into the dictionary they are stored in your computer's main memory, and are NOT placed in the disk file "words.txt".

If you choose to update the dictionary by pressing the left mouse button in the "yes" box, the new words in main memory will be inserted into the file "words.txt". When the program is done, "words.txt" will contain all the words it had before running SPELL, and also the new ones you inserted. When you run SPELL again, it will know that the new words are correct, and and will not ask you about them when it encounters them.

If you choose not to update the dictionary by pressing the left mouse button in the "no" box, the file "words.txt" will not be changed - it will have the same words that it had when you started running SPELL, and will not have the new words that you inserted when SPELL was running.

FOR MORE INFORMATION:

If you would like more information about SPELL, please send a stamped, self-addressed envelope to the following address:

        As i reported to the list some days before, we had problems
        with the uuencoded files too. We located the problem in our
        EBCDIC --> ASCII Translation-Table. Looking around i found
        some other obscure tables. So some sites like to do a
        "visual - replacement". This means that for example the
        ASCII ! (exclamation point) ist translated to the EBCDIC
        | (short vertical bar). At our VAX there are two different
        Translation Tables (supported to choose at generating).
        So if a site in the (Bit-)Net is using the other table .....

        So i like to propose that people who are sending uuencode files
        may support an additional line, which shows the used characters
        in the ASCII-Order. ( I think in UUENCODE this are the chars
        between 20hex and 5Fhex in ASCII)

        for example a line like the one below

 !"#$%&'()*+,-./0123456789:;<=>?@ABCDEFGHIJKLMNOPQRSTUVWXYZ[\]^_

        starting with blank, may be very helpfull to decide where from
        troubles come.

        So with such line everyone could see, if there are some chars
        double, or the chars ar not in the ASCII-sequence, that he could
        save the time for transmitting the file to his ATARI

> Bob Menton
> MENTON@NRL-ACOUSTICS

In June, Atari threw in the SS disk drive free to dealers ordering the
monochrome system. This is what brought the price (sale) down under
$500 at several mail order sources and some discount stores. As I
understand it, the deal did not apply to color systems which is why
you didn't see a corresponding drop in prices of color systems. Probably
most of those systems are sold by now. A sale price of $549 is very,
very good if the dealer had to pay normal system price to Atari. I
have not heard of any price increases but Atari is trying to get the
EST system out by Christmas according to Current Notes and it will
cost more than the 1040ST. I would think that that would drive the
price of the other systems down slightly, but not guarantees.

I just aquired version 1.06 of First Word and the only difference I can find
(from version 1.04) is that 1.06 DOES NOT work with Thunder! Two questions:
1) Anyone else find this problem? [It doesn't backspace correctly] 2) What
positive changes were made to 1.06 - I can't find any. Maybe GST and/or
Atari plan their own checker and this is sleaze marketing.

>John Norman

I am one of the beta testers of SEDT, and have been using it for a few weeks now. Although SEDT is still in beta test, I find it to be unusually free of bugs. I feel it has EDT beat, and I've also now switched from using EDT to SEDT on my VAX at work. I consider it a real plus to be able to use the same editor on the VAX and on my ST at home. Also, its especially comforting to have such a high level of support from Anker - his response time to enhancements/fixes is fast! He recently spoke on SEDT at our local Atari club meeting.

Regarding the current status of SEDT, I'm including a message from him, below, that was extracted from our in-house NOTES file:

> I have been plugging away at it. Have what I think is a very solid TOS version. The only annoyance is the time that it takes for me to checkpoint the journal file, which has to be done by closing and reopening it again.
>
> I was given strong input that a GEM version was highly desirable and have taken that advice. Finished a first cut this weekend and feel very good about it. I need to enhance some of the menus, but it looks good. I'll get this out to the betatesters in about a week.
>
> Finally I have to get some feedback from the betatesters on where the product needs improvement. Having done that I should be ready to go to market.

<<<<<>>>>>

Hello again,
  In response to my question about running THUNDER! and a GEM-type terminal emulator a kind soul posted a note about Grafikon Ltd.'s ANSIGRAF. This program is supposed to do VT102 and Tektronix 4014 as well as being under the GEM desktop.
  Question: Does anyone know how I can get ahold of Grafikon Ltd.? A phone number and/or address would be enough BUT if anyone has used this program with THUNDER! that would also be a great help. Any information about Grafikon Ltd. and/or ANSIGRAF including pricing/availability etc. will be greatly appreciated.
  Thanks for all the help.

                  Bob

I will quote from an article in the September issue of Currrent Notes
which I just received:

"As this is composed, the decision ostensibly sits on the desk of the
President of Apple Computer, John Scully. If it's thumbs up, the
cartridge could move rather rapidly to the market, and be a vitiamin
"M" (money) motivational boost for Apple developers because it would
expand their potential market by another 250,000 machines and growing.
The chances of Apple recognizing the value of this, and/or deciding to
give a competitor, the ST, a leg up appears slim at this juncture."
                        -Current Notes- 9/86

Hope this helps...

>                           MENTON@NRL-ACOUSTICS

The $495 price quoted here *was* a sale price.  It was a special promotion
that Atari offered last summer and it ended August 1.  There may be,
according to sources at Atari, some dealers who bought in on the deal
at the the end of the offer and they may still have some systems to offer
at that price.  The dealer in VA may be doing that and getting an extra
$54 out of of (I say *MAY* - I have no information on this, it's pure
speculation - the dealer may also just be offering a dynamite price).
At any rate, this does not reflect any price increases from Atari on
the ST.
```

While I'm here: This is probably my last posting on the net. Today is my last day with my employer and I don't have any idea if my next job will give me access to usenet. I have greatly enjoyed reading and interacting with the net and I appreciate both the information and sources contributed by net people and the opportunity provided by those organizations who make the net possible at all. Thanks, all. See you around.

Sweeney

Hmm, let me try to simplify the problem.

     Since most of this conversation happens because of the introduction of Un*x flavored facilities, I will try to explain in Un*x terms.

     When people produce programs, especially in C, on Un*x systems they tend to do them in multiple source files, usually with a 'makefile' (command file for the make utility, but make is another article (:-) which depends on the files having the right names and being in the right places.

     To mail these files around to other users on the net, the source files are placed in encapsulated form. However, simply stacking them

all together in one file leaves the recipient with the problem of unpacking that file into all of the smaller files.

So, a format called shar (short for shell archive) was invented, which is simply to encapsulate each of the files into a huge shell script (Un*x command file) which the recipient simply feeds to the shell to get all of the files where they belong.

To simply the process even further, there are number of public domain Un*x utilities floating around which will do the packaging for you.

A related problem is that some mail systems have an upper limit on the size of a mail message they will transmit. This leads to the '1 of n' mail messages you sometimes see (like the source for uEmacs.)

The problem with just sending sources is that not everyone will have the compiler that you used to produce the software. (I for instance don't have any C compiler yet, having not figured out which one to buy (:-() So some people will send the executable image.

Since the executable is binary data, any byte in it can have any of the legal values from 0 to 255 (assume unsigned) but the ASCII character set is officially only from 0 to 127 and many implementations will strip off the high order bit when sending data over terminal lines.

Also, many mailers have problems with 'nonprinting' (or control) characters, some of which are treated especially. The solution to this problem is to encode binary files such as executable image into various formats in which the results are all 'printing ascii' characters.

uuencode and uudecode are opposite ends of this chain. uuencode encodes the file (the 'uu' is because they were intended to be used by uucp on unix systems) and the uudecode decodes them on the other side.

uuencode also calculates a checksum which uudecode checks. This gives you some assurance that nothing went wrong with the file (like a bit getting flipped by a noisey modem) during transmission along the mail system.

Another complexity which you didn't mention is how you get the file from the mail system or buletin board computer to your ST. There are two (or more?) competing mechanisms for transfering files, both of which were designed to get around limitations and problems in using terminal (RS232) lines to transmit data.

The first is the *MODEM (for * = x, y, z) family of protocols, first invented by Ward Christians in the early '70s for use between microcomputers. There are public domain XMODEM programs for most computers, as well as XMODEM facilities included in most 'communication programs'. If you want to get files from buletin boards, you'll probably need XMODEM, since most buletin boards use it.

The second is KERMIT, a protocol invented at Columbia university, and placed in the public domain. Again, there are KERMIT implementations for most computers, and some of the communications programs include the KERMIT protocol.

If you try to get files off of buletin boards you will also discover that there are alternatives to shar for archiving, to uuencode/decode for decoding, and all about tools for file compression; but that's for another discussion (;-)

Hope this helped more than it hurt.

Marty

According to the Sept. issue of "ST Aplications" :
P.O. Box 446
College Park, MD 20740
301-937-3394

Price is listed as $79.95.

The usual disclaimers apply. In fact, I noticed that this same publication
list OS-9/68k as a "generic CP/M". How could anyone be that wrong?
So, take this information with a whole salt shaker.

<<<<<>>>>>

  I worked up this version of uudecode for the ST after getting
the turbo pascal version to work on my PC. It is the full
featured version, except that it will write only even numbered
binary files. This is because OSS Pascal can only write integers
to files and an integer is two bytes. This is not a functional
problem, only a theoretical one.
  The original author should probably stand forward, as should
the copywrite info for OSS Pascal, but since this is the net,
and you need the Compiler to get it running, I think it is
good enough.
  I don't guarantee anything other than it works for me, and it
does use the GEM interface (I added that). If you need the
executable then mail me at the address at the end of this posting,
I will try to work something out. Have fun!

> ......

I found some hints in the "Hitch' Guide" and played a bit with SID.

BIOS call "getmpb" is a special system call provided for GEMDOS use
only (parameter passing between BIOS and BDOS).
"getmpb" is called only once at boot time by GEMDOS to get its initial
memory management structure.

The first "getmpb" call initializes a BDOS structure at 0x56ec of type MPB
with { 0x48e, 0, 0x48e } and a memory descriptor at 0x48e of type MD
with {
         NULL   /* end of list */,
         0xa100   /* _membot */,
         0xedf00   /* _memtop - _membot (520ST+) */,
         NULL   /* owning process is system */
      }.
The memory descriptor at 0x48e is the initial single element free list for
the GEMDOS memory manager.
The first time, Malloc() is called, the MD at 0x48e is removed from the free
list and is inserted into the allocated list modified to the requested block
length. For the memory left a new MD is created and inserted into the allocated
list.
Insertion is done by putting the new in front of the existing elements.
This causes the MD at 0x48e to be the end of the allocated list and no Malloc()
call will change it.

Calling "getmpb" in a user program (panic !!!!!!!) modifies the last MD
in the allocated list.
Probably this has no effect to the memory manager because the modified MD
was originated for system memory which is never released, but who knows ?????

I wrote a little program to print the memory descriptor lists. It might be
useful, if you have memory fragmentation problems. Enjoy .....

Summary: Yes, sometimes the patent office gets wacko

In article <6985@sun.uucp>, ludemann@sun.uucp (Jim Ludemann) writes:
> I hate to tell you folks, but Andy Bechtolsheim here at Sun has a patent
> (applied for and granted) on using the untranslated addresses as the
> RAS addresses and doing the MMU address translation before the column
> addresses are needed for CAS. Sooner or later, it's going to cost some
> competitors a WHOLE lot of money.

Yes, folks, I can believe this man. I have in my office right now a
patent (which has been successfully contested) on xoring cursors into
a frame buffer, so they can be easily erased. The patent also apparently
applies to rubber-band lines in xor mode.

I also have another one (can you believe this? it's true!) on the
transformation equations for perspective projection on a display screen,
and their implementation in a digital computer. This one has also been
fought, and although the original scope of the patent was much reduced
(the guy can now only soak you if you use HIS FORM of the equations), the
patent was upheld, not once but several times (I have a sheaf of court
documents all about this case - if you're interested in this sicko stuff
mail me and I'll provide references).

I don't have the numbers or the authors right here, but if you're interested
I can mail them to you.

It's a mad, mad, mad, mad, mad, MAD world.

Address is: Grafikon, Ltd.
Attn. R. Kulkarni or G. Fekete
P.O. Box 446
College Park, MD 20740

Phone (301)-937-3394
Price: $79.95

There is a nice three page review of the program is September 1986 issue
of Current Notes (newsletter of the Washington Area Atari Computer
Enthusiasts). They do not address the problem of using a real time
spelling checker. Sorry...

A friend of mine has asked me to track down a driver
for his Epson LQ1000 printer. His problem comes in
making screen dumps with his 1040ST, as his printer
has 24 rather than 8 pins in the print-head.

If anyone could send me such a driver or provide a
pointer to one, I and my friend would be most grateful.
(This is the sort of problem that I would normally
handle myself, but not even OWNING a printer, I don't
know where to start.)

Thanx in Advance --   M. Brinsmead @ University of Calgary

Hello,

Who can send me a UNITERM program.
I just recently joined the atari16. If it is not
poosible to uuencode it with the kermit uuencode program

(from CUVMA) would you please alse send a encode/decode program
preferably written in Lattic-C.
I understood this program also emulates a VT100 terminal.
I bought the program FLASH from ANTIC. They say it emulates a VT100
terminal but some commands are not understood by the program.
E.G. When working with the edditor on a VAX 11/750 in
full screen mode, the lines at the bottom are not scrolled.
Insertion of lines is also impossible.
If somebody else has also encountered these problems (and probably had
it solved) please leave a note.

Greetings,
Berend F. de Vries.

Does anyone have any hard information or informed speculations about the future of GEM? Specifically, is there a multitasking GEM in the works which will fully exploit the resources of 68020 machines? I am sure most of us would love to see many of the best features of the windowing and operating systems of Symbolics, Sun, Apollo, MicroVAX, and Xerox 6085 workstations integrated into a GEM or GEMlike interface on the next generation of Atari machines.

Also, will it be possible to run Windows with the new IBM PC emulator for the Atari, and, if so, might not Windows and eventually MS-DOS 5.0 become the operating system of choice for Atari users and programmers?

One of the utilities I haven't seen yet is a "CHKDSK" for the ST.
I'm almost sure that I have diskettes with broken FATS which could use
a run of a CHKDSK like the MS-DOS'ers have. Has anyone seen a utility
which fixes FATS?

   In my pounding on the keyboard these last months, I've come up with the
following observations, questions, and frustrations. They seem to amass
on little sheets of paper and every month or so I have this catharsis

and BLOUMPH, they come out as netmail.

MAKE:

I've experienced problems bringing up the recentnet-distributed make with the developer's kit. Besides the reported problems with VOID, my malloc (UNIX's memory allocator, with a small m) seems to have no memory available for it. Things went farther with Malloc (GEMDOS's memory allocator), except it barfs parsing blank lines and comment lines. With those edited out of the makefile, then Malloc runs out of memory. I'm now thinking that small m malloc is the one, but my GEMSTART is out of date (I got my kit around 4/86). Anybody been down these rat-holes too? (and maybe know the way out?)

REPORTING ERRORS:

I have modified make's FATAL routine to pause for a while so you have more than 50ms to read the error messages. Much GEM PD software has this problem. Why doesn't ATARI give us at least 200ms so the image can implant on our retina?

839K DISK FORMAT:

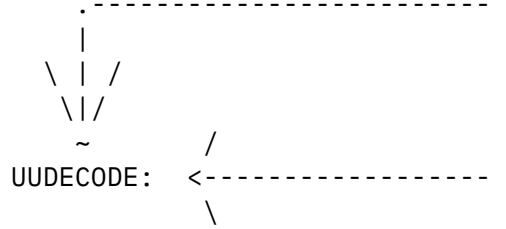
Just found the 410K formatter, which actually gives an extra 113K on double-sided drives (839K vs 726K). It lets me actually put all of my mandelbrot demo and compiler and linker on one disk! Do all the desktop utilities (such as copy) work with it? How is it that Atari doesn't use it?

RENAMING DIRECTORIES:

Anybody got a program or accessory to rename directories? Its a pain to creat a new one and copy things around. The copy program I asked for a few months ago was received and is well used -- every compilation I do.

FLIGHT SIMULATOR:

Would somebody recommend a flight simulator for the ST? What's available? Has anybody had good or bad experiences?



uudecode has been giving me *FITS*. I've tried 3 uudecodes on 2 files

i've gotten over the net. Nothing executes properly. What is less, (almost) none of the lengths agree.

	circle2	accdemo.acc
uudecode from some kind soul who copies disks	49710 (bus errors)	12032 (won't boot)
uudecode assembled from the recent net sources	25961 (bus errors)	12165 (won't boot)
uudecode on VAX/ULTRIX downlined with kermit	25728 (can't download)	12032 (won't boot)

BULLETIN BOARDS:

I've dropped back to using bulletin boards for the moment. I'm also about to release a fast interactive Mandelbrot demo, and can't see putting 80K of binary over the net. So here is the list of bulletin boards I know of (not all of which I've called):

ATARI:	1-408-745-2642 -4758 -5360 -5970 -5664
Computer Club II	1-313-334-8877 (Detroit)
(Fresno)	1-209-292-1777
(?)	1-312-283-0559
(?)	1-219-277-5825

Does anybody have a more complete list? Post it, or send me mail (aking@bfly-vax.bbn.com, possibly prefixed with ucbvax!, possibly prefixed with ucbcad!.) I'll accumulate responses for 2 weeks and then post. Seems like a good way to keep from getting reams of uuencoded printout in my net-mail printout. (I read it in the car at stoplights as I commute, and the discarded sheets of "M\$ZY'''N7CX\'*5!..." mess up my car!) Seriously, I'd like to see more mail of the form: "I just placed the following software with the following great features on the following bulletin boards: 1-617-...".

Also, would the guy who was going to be moderator (was it) of a sources something or another (remember all the mail on choosing its name?) post some status and "wake-up call" so we all know whats going on.

KERMIT:

What features does the new KERMIT have? does it offer remote operation (where you only have to go upline once to login) ? Hows about some statistics display like XMODEM has as the file is transfered? Are there bulletin boards around with the new KERMIT and uEMACS on them?

uEMACS:

Same question, uEMACS 3.4. Color, did I hear? and ^x^f like real EMACS!

(wanta know how to blow a file with 2 misplace keystrokes: Think youre in real EMACS and go to get a file with ^x^f. But you sit in uEMACS

and the disk doesn't spin. So you go to hit ^x^v to do the right thing, but you know Z is right next to X, and ^z writes your old file right on top of the one you wanted to get and then quits. P O O F ! (Did they think they were making it better?)

Greetings,
  I remember coming across a rather complete and well done description of the uuencode/uudecode programs, and I neglected to save a copy of it. Well, I update a LARGE number of notesfiles, and I seem to have lost track of where it was (or might have been, public notesfiles on this system are cleaned often due to space limitations, and I think it might have come from this digest. What Im getting to is if this letter was posted on this digest and someone has it, would they be kind enough to send me a copy (and if it wasnt here but you know what Im talking about and have it and would be kind enough to send it)? Thanks either way.
                                                                -Steve

As for my earlier message as why my TextBlt did not work, I may have a clue. It turns out that the problem (I think) was in the size of the raster form width. I was using a form with a width of 4096 bytes, so maybe a signed word value may have had problems. I tried using a form with a much smaller width (the system font), and it worked fine. So, then I tried a form width of 2048. Nope, still didn't work. Hmmm...

So, right now, I take the character I want, blit it from the big form into a temporary form, and then TextBlt it. This works! It is interesting to note that normal GEM raster ops work fine with raster form widths of 4096 bytes. I wish I had some documentation that explained this for sure...

Also, I would like to thank Jwahar Bammi for his replies to my TextBlt questions. All of my letters got bounced back from case, so I couldn't thank him personally.

So, if anyone has any definitive ideas about this TextBlt/form width thing, I would love to hear about it.

Summary: A great incrementally compiled BASIC coming soon!

[]

Kevin J. Burnett wrote:
>What are good inexpensive ... compilers for the ST?
>Also, ... in ST BASIC...

Well, it took me very little time to abandon ST BASIC - it's got 3 windows too many (it is faster to retype one line than use the "screen" editor, and so on) and in the 250 page manual I couldn't find any hint on using the RS232 port (I'm sure it's possible, though) and it's SLOOOOOW, etc...

Those of you interested in BASIC, the langauge and/or the interactive environment, will be happy to know that an incrementally compiled, BASIC-like language is about to come out for the ST. Incrementally compiled means that each line is compiled immediately upon entry (which is so fast that you don't notice it) (and decompiled if you LIST, again fast - THAT is what the magic power of the 68000 is for) - and when you want to RUN the program the compiled code is ready to run, and run FAST! (The infamous SIEVE - n=8192, 10 iterations - takes about 25 seconds, or about 30 times faster than ST-BASIC, and faster than all the BASIC compilers too.)

The language, called HBASIC, is not quite standard BASIC, though.
(It is not a GEM program nor a GEM-compatible system, either!)
Data types include integers and reals (distinct!), strings, and arrays.
Floating point is double-precision but FAST. I don't know what graphics capabilities will be included in the early package, if any. Disk access bypasses TOS and is VERY FAST. A RAM-based assembler will be bundled with it, and there's access to assembled routines from HBASIC.

This is NOT vaporware, it is running now and the first public release is scheduled in about two months. It is a descendent of HALGOL, the language that runs on the 68000 add-on boards called "Dtack Grounded", that attach to Apple][' s and IBM PC's.

All of these HW/SW products are made by Digital Acoustics, inc., with which I am not at all associated. The price will be about $50, but I'm not sure if that will include the assembler. This info is out of the newsletter they sent to some of their old-time customers.

A quote from "ST internals" (the Abacus book that us traitors who
refused to spend $300 on a mediocre C compiler + some IBM-PC-GEM docs
have to live with until X-MAS):

> "The bit-block transfer is used by the text-block transfer...
> A6 must contain a pointer to a parameter table. Unfortunately, the
> construction of this parameter table could not be determined...
> Our attempts led to classic system crashes... we cannot say much
> about the function."

And I presume they did have the developer's package...

One of the wonders of the information age is that people go into so much
trouble to create software, but then neglect to disseminate (or create)
the information that would make it useful. Happens every time!

I'm doing some graphics-intensive stuff on my ST, using Megamax C. Some of it involves animation, and it really looks bad to draw elements of the output piece by piece. The time taken is significant, and it would be a great improvement to draw the whole thing off-screen, in some phantom area, and then reset the screen position. Then the new drawing would just "blink" into place. But as far as I understand it, the drawing routines (v_pline, v_fillarea, etc) work only on the current screen. If anyone knows a way around this problem I'd appreciate hearing it.

I hate to tell you folks, but Andy Bechtolsheim here at Sun has a patent
(applied for and granted) on using the untranslated addresses as the
RAS addresses and doing the MMU address translation before the column
addresses are needed for CAS. Sooner or later, it's going to cost some
competitors a WHOLE lot of money.

Has anyone had any experience using the okimate 20 color printer with the
ST? There is a rather useless review in the October issue of Antic. Is the
printer driver supplied with it useable for monochrome screen dumps? I think
that other okidata printers emulate epson graphics, does the oki 20 provide
any such capabilities? Also, what is the print resolution? Does it support
italics, superscripts and subscripts and the like? Any general impressions?

>Jeff Gortatowsky   {allegra,seismo}!rochester!kodak!elmgate!jdg
>Eastman Kodak Company
><Kodak won't be responsible for the above comments, only those below>

Well i admit it takes some digging around, but all the info is certainly
present. The 300 bucks are more than well spent. The bit block info is on
pages 775-789.

Ok here are the details:

B_WD width of blocks in pixels
D_HT height   "   "

PLANE_CT # of consecutive planes to blit

FG_COL & BG_COL   fg and bg color

OP TAB (4 bytes) {
     logic op to employ when FG=0 and BG = 1
                    FG=0   BG = 1
                    FG=1   BG = 0
                    FG=1   BG = 1
          } (one of 16 logic ops)
S_XMIN , S_YMIN   minimum X & Y source (in pixels)
S_FORM   source form base address (must fall on word address)
D_FORM   destin "   "   "   "   "

S_NXWD and D_NXWD offset to next word in plane of memory form. Mono = 2.
            Med = 4, low=8

S_NXLN and D_NXLN form width for source and dest. These widthare even, they

represent the offset from one row of the form to the next.
Hi rez (mono) = 80, low and med rez = 160

S_NXPL and D_NXPL offset from start of one plane to the start of next.
Always = 2

The pattern parameters (P_ADDR P_NXLN P_NXPL) are similarly defined.
Also there is that 26 byte buffer at the end that is used and does not
need to be initialized before the call.
Also see the description of MFDB in anything that describes Vdi and the
above will be quite clear. I can recommend "Gem Programming" by Balma and
Titler highly.

Hope that helps,

Summary: Is this a nightmare?

[]

To whoever organizes this: Please add my friend Larry Bank,
<oykj@cornella.BITNET>, to the distribution list of net.micro.atari16.

Thanks!

BTW, when I learn't that on IBM mainframes you get this news as PERSONAL
MAIL, I fell over backwards. Does that mean that for every reader on the
same machine, a separate copy is mailed? It at least means that a separate
copy is stored, which would make the system administrators soon buy some
more disk drives...

For those of you who don't know: on (some) UNIX systems you read the news
by typing a command (e.g. "readnews"). The system knows which newsgroups
you "subscribe" to, and shows you that stuff, of which I presume there is
only one copy in there. The "readnews" program also allows things like
"mark item as (un)read", "show list of posting with subject line", "show
a specific posting", "post followup article", etc - all invoked by pressing
ONE KEY.

Keywords: Does it work? My attempts didn't

Does the ST support NDC (Normalized Device Coordinates)? I've seen one
source that says it doesn't and one that mentions NDC as a possibility,
which presumably means it does. Neither source is just a real fount of
reliable wisdom, though; one was the TDI manual (not quite useless, and I
do like Modula), the other was ABACUS Books' GEM_Programmer's_Reference_Guide.

So, what is the real story? I tried to get an application to run with NDC
and I got bombs instead. Am I missing something, is TDI missing
something, or is the ST at fault? Really, of course, Atari is at fault
for not providing useful documentation at a reasonable price. (Sorry,
Neil, but I just can't resist a chance to *slam* that point home to the

marketing wizards at Atari *one* *more* *time*   1/2 :-)

Working in the dark,
Doug Miller

        We got some troubles tooin using uudecode.
        As reason we found an error in our local
        EBCDIC --> ASCII Translation - Table.
        So i propose those people, who have toubles too,
        try to look in the uuencode files if there are
        all possible chars (i think between blank and
        uppercase Z) are represented. At our site the
        ^ (circumflex) got to a ? questionmark. In this
        situation we found that at a DIGITAL VAX there are
        two Translation Tables to choose by generating.
        (So we have there two modifications belonging to
        the brackets [] . Which not worked with the defaults)

In A. K. Dewdney's "Computer Recreations" column in the September 1986, Scientific American he describes several Mandelbrot inspired programs. I've implemented the first of these, John E. Connett's CIRCLE2 in OSS Pascal. It draws the pattern in a small window in the upper right hand corner of the screen. A menu selection called "Commands" allows you to adjust the parameters of the function as descibed in the "Computer Recreations" column, as well as adjust the aspect ratio and number of colors used to draw the patterns. It has been tested on a color monitor, but I believe it will work just fine on monochrome.

This message contains the source for my implementation of circle2 and the following message contains the uuencoded binary (for those who don't have OSS Pascal and are able to uudecode successfully...).

Thanks to Dennis Vadura for pointing me in the right direction on
my uudecode problem. I looked in the C sources for uudecode that
I had received from Columbia as part of the new GEM Kermit
distribution. Sure enough, it opened the binary output using
fopen(<name>, "wb") . In Alcyon C, this must be replaced by a call
on a different function: fopenb(<name>, "w"). Similar changes must
be made to uuencode so that its binary input is opened properly.
(Of course, one must also remember to declare the new function.)
After making the changes, I had no trouble in decoding the Kermit
resource and executable file, and they work fine. I'm looking forward
now to decoding uEMACS 3.7 and other goodies that have been
accumulating on the net.

>which presumably means it does.

No, the Atari roms do not support NDC. Atari/DRI did not have room enough
in the ROM's to include the device independent part of the VDI. That is
also the reason why you cannot load fonts with the standard vdi functions
and why there is no official version of GEM Draw and GEM Write. (They use
the device independent part very much for different output devices).
One solution is to intercept the trap#2 (AES, VDI trap) and supply the
the missing parts of VDI. This is what GDOS does (used by Easydraw).
There have been announcements of an official release of GDOS but I have
not seen it yet.
An excellent background story is in STart, The ST Quarterly, Summer 1986
by Tim Oren: Tracking the elusive GDOS. Get hold of it and read it.
Hope this info is useful

Most of binaries I undecoded from net postings work on my ST. Even
'cadenza' :-). Some of them I even managed to decode on VAX and
transfer as image files to ST. This depends on a phase of the moon and
good humour of 'kermit' programs on BOTH ends.
Not so good luck with emacs3.7.   I checked uudecoded files on VAX and
ST. They are exactly of the same length. Neverthless the program bombs
out with "#4 - Illegal instrunction trap". Is it cuased by a fact that
I tried to run it on a color monitor?

How the hell can the patent office grant patents like this? It's sort
of like patenting the idea of grounding DTACK on a 68000 or putting
chocolate ice cream in root beer; the idea is too obvious. To coin a
phrase, it's patently ridiculous.

Does anyone out there have a version of uncompress that runs on
the ST? If not, does anyone have the specs so I can write such
a program?

Some binaries were sent out in compressed form a while back, but
because I don't have the uncompress program (and because whoever
sent them out assumed that all of us use unix-based mainframes),
I can't do a thing with them. :-(

Thanks in advance,

>Has anyone else successful uudecode anything and had it run on the ST?

  I have had excellent luck with uuencoded stuff. The only two problems
I remember were with a Forth interpreter (an early version of Bradley's
FORTHMACS) which came in four parts and never has worked, and the 'Piano'
package from Scott Huskey, which was simply broken (but the new copy he
sent me by mail works - thanks, Scott!).

  I capture the stuff and squirt it to my ST while still uuencoded,
downloading it as straight ASCII with FLASH!. I then uudecode it on my
ST. This even worked for Hack for the ST.

  Caveat: I haven't tried decoding the MicroEmacs 3.7 yet, and I didn't
get all of the Uniterm binary. But other people have had success, so...
I'll send my source for ST uudecode to anyone ; drop me a note if you wish.
(Or maybe I should send uuencoded binaries? :-) :-) :-))

   The First Northern California Atari Expo will be held September 20-21 at the San Jose Convention Center. Tickets are $5.00 a day at the door or $3.00 a day through user groups. The show is exclusively for Atari products and companies from around the country will be there showing their products for both the 8-bit and 16-bit machines.
   Atari will have a booth for hands-on demonstrations. The Expo is being sponsored by the Bay Area Atari Users Group (BAAUG) along with SLCC, ABACUS, & DACE. Look for new hardware and software from more than 50 developers. There will be door prizes and speakers from around the country as well as a major production from Atari Corp itself.
For 24-hour information call the BAAUG BBS at 408-249-7722. Or write to the NORCAL EXPO Executive Committee at:

             Northern California Atari EXPO
             Suite 280
             P.O. Box 9018
             Walnut Creek, CA 94598-0918

   In the evenings call Rich Anderson, 408-281-8139. Pass the information along to your user group!

I wish to know if anyone has successfully interfaced an analog RGB monitor
to the Atari 520 or 1040. In particular has anyone used the Magnavox?
I have seen reports in COMPUTE that indicated SONY had trouble interfacing
their analog RGB monitor to the ST and has had to actually design an electronic
cable interface. Has anyone had experience in this area?

I have also successfully uudecoded ue 3.7 and kermitted it to my ST.
I used GEM Kermit (which I uudecoded and kermitted with the kermit
that came with the developers kit). So far, I haven't experienced problems
with uudecode or kermit (or kermit at 1200 baud over an Avatex modem
for that matter). Just make sure and use image mode on both ends.

> It appears to work on my mono screen, though it appears to be
> set up for 43 lines (EGA PC screen) so you need the little HI50
> program to get it to work.

   What is this HI50 program that solves the 43 line problem?
At the moment, I make ue work by opening another window whose
length can be adjusted to a physically realizable dimension.

I seem to have a problem with the numbered macros (in the emacs.rc that came with ue). The keys are bound, but when I push them, they can't find the macro. The "help" macro works when I type ":help".

It also seem that lines in the resulting text files are delimited with only a line feed (instead of line feed/carriage return) which shows up when I double click a test file and "show" it. Does the original do this, or was something lost in the translation?

Nonetheless, this is an incredible improvement over the editor that came with Lattice C.

Thanks,

Wayne Smith

Finally!!!!!!
I GOT A UUDECODED PROGRAM TO WORK! I was trying to get Simon Poole's UNITERM to work and kept getting TOS ERROR #35 as others have noted. When I catted the three files together I did not check the end of each unsharred file. It turns out each file had two blank lines at the end. I deleted these lines and voila it works - I'm using the VT100 emulator even now.

There's been a lot of UUENCODEd stuff on INFO-ATARI16 recently. If you're on an IBM system running VM/CMS, you will have two problems with raw UUENCODEd files:

(1) Trailing blanks will be removed when the files are shipped over BITNET.

(2) Trailing blanks will be removed if you use VM/CMS Kermit to transmit the files from VM/CMS to your Atari ST. (Try it and see!)

I have written a version of UUDECODE that ignores the absence of trailing blanks in a file to be UUDECODEd; using it, I have been able to decode most of the UUENCODEd stuff that has been posted this summer.

The program is written in assembly language and as a result is much faster than, for example, the UUENCODE distributed in Franco's starter kit. It can be assembled with the public domain assembler, AS68, which can be found in Franco's starter kit or on the Atari BBS. This assembler does not assemble register shifts, so all the register shifts in the code have been commented out and hand-assembled to dc.w's.

Subject: HEEEELLLLPPP with Kermit sources

I've got a listing of the Kermit source code here, and I have a bit of a
problem in trying to figure out a couple of things here, due to the fact
that the listing was made on an IBM 3800 laster printer, which prints stuff
out in EBCDIC. This means that there are two places (that I have come
across so far) where I can't tell what the character actually is.
There is one place where in the listing there is what looks like a dgree
sign (like a superscript o), and another where there is a logcal NOT sign.
The problem is, both of t
type out the file on my ASCII (ST) terminal.
  Does anybody know what these two codes should map into in ASCII?

No Problem... I uudecoded it on our vax (BSD4.2) then
used kermit to send it to an ST.
I've never had a problem with uuencoded binaries using this method
You need a kermit in the ST which supports binary (image) transfer
mode. The version in the developers kit does that ok.
What methods are others using?

On U-emacs 3.7 though... I found it worked fine on a colour monitor
but not on te monochrome one I use at home.

Keywords: They don't work together at all!

<<<<<>>>>>

This is a followup to the article that I posted about the
use of THUNDER! (copywrite Batteries Included) and the VT-52
desk accessory. I was told that it might work (and in one case
was told that it was used 'all the time') so I went ahead and
purchased it for around $35.00.

To make a long story short, it does not work at all with
the VT-52 desk accessory. It MUST have the normal desk top-like
menu bar at the top of the screen to work properly. Even so,
when I tried it with a tektronix 4010 multiple screen terminal
emulator the I wrote that uses the menu bar and the like, it
didn't work either. So it seems that just having the menu bar
is not enough. I tried talking to the people at B.I. and asked
them if they know of a terminal emulator that would work with
THUNDER! and they didn't know of any.

I*S Talk (I have heard) emulates a vt-100. Is there someone
who has this program that could verify this. Please! don't
respond if you just think it might - I already have one $35
program that I have no use for. The people at B.I. (I*S too)
didn't seem too knowledgable about the terminal emulation

features of I*S Talk, this is why I am asking.

Please respond all you I*S Talk users, I really need an on-line
spelling checker as soon as possible. As always, thanks in advance,
but PLEASE make sure that you know for certain the information
you pass along - I don't need to keep B.I. in business buying
programs I don't use.

Bob

Please forgive me for my ignorance, but would some kind net.hacker explain
a few things to me? I bought a 520st several months ago and have been
using it mostly to help me with graduate work (i.e. word processing, charts,
graphs, etc.). I have recently acquired a modem to use so I can dial-in
to the systems at work. I am fairly baffled by all the talk on uuencode,
uudecode, shar files, sources vs. binaries, etc., and I feel like I am
missing out on some great software because I don't know how to down-load
the stuff to my machine. Would someone please give me some definitions,
procedures, etc. or recommend some other source for this info? Please
reply via e-mail. Thanks in advance.

I have had to SMM804 printer for a few months now without having any problems. It seems to go through ribbons fast, but I did quite a few screen dumps when I first bought it. The speed is 80cps. It is bi-directional. It is a graphics printer and, I think, the same as an Epson lx80 under the cover.

I have a couple of questions that I hope aren't too inane:

1) Is 1ST WORD free or not? I know it's currently shipped with the 520ST, but can just anyone make themselves a copy of it? I've seen a place *selling* the word processor for (I believe) $34.95. What gives?

2) What is the size of the memory area set aside for ACCessories? Or is there a numerical limit on the number of accessories you can have at one time: i.e., you can only have 6 desk accessories? A friend, who has TOS in ROM, gets 380-odd K memory when he runs FREERAM with a PD CALCULATOR, CALENDAR, PALETTE CHANGE, CONTROL PANEL, and INSTALL PRINTER as accessories. Is *that* much memory required for the accessories? And, is there any way to remove the INSTALL PRINTER to make room for another accessory? I got rid of his VT52 emulator (he has FLASH!), but I couldn't find any ACC file for INSTALL PRINTER.

Thanks for any help.

Thanks to everybody who sent me comments or requests for UniTerm, a few nasty bugs have turned up during the last three weeks (due mostly to me not having a test program (I've got one now)) most of them are already fixed (GINMode, Tabs etc.). I will send a updated copy to everyone who has already sent me a message sometime this or next week (I'm really on holidays).

1) There are two versions of 1ST WORD, the one that comes with your
   system and one called 1ST WORD PLUS. Neither of them is free, as
   I understand it. 1ST WORD is bundled with the system, but still
   belongs to Atari. 1ST WORD PLUS is (will be?) available at an
   extra cost.

   Since 1ST WORD comes with, the dealer should have been selling
   1ST WORD PLUS, but. . .(?)

2) The limit is numeric. You can have no more than six desk accessories
   loaded at once. A gotcha is that some desk accessory files contain
   more than one desk accessory. This is true for both emulator.acc,
   which contains 'VT52' and 'configure rs232', and control.acc, which
   contains the 'control panel' and 'install printer'. To do away with
   'install printer', you also have to do away with 'control panel'.

   There also appears to be no way to unload a loaded desk accessory,
   other than changing the .ACC to something and rebooting.

>of like patenting the idea of grounding DTACK on a 68000 or putting
>chocolate ice cream in root beer; the idea is too obvious. To coin a
>phrase, it's patently ridiculous.

If it's so obvious, why didn't anyone think of it before Andy did?
Is the Set-UID bit (also patented) any less obvious? Not to me,
now that I've seen them both. But I never thought of them; neither
did anyone else, evidently, before their respective inventors.

The person who first put chocolate ice cream into root beer probably
didn't realize what they'd done. They should have patented it, too!
(Unless, of course, someone had already done the same thing with
vanilla ice cream. Then *they* should have pattented it.)

The real question, to me, is (since the original poster suggested that
Sun's competitors would have to start paying for this idea) Who really
owns the patent? The idea was developed while Andy was at Stanford,
possibly (I have no idea, one way or the other) with public money.
If it was developed with Federal money, then policy says that there
will be no fees for use of the patent. If Sun owns it, then there
probably will be fees.

Some mailer somewhere completely ruined that posting. I got a copy
off the net, unpacked, and od'ed the binary. Parts of it were correct,
and other parts were totally hosed.

BTW, if you don't have Forthmacs yet, get a copy and try it out. It
has a disassembler, assembler, memory display/modification, interactive
file access, a command interpreter, MicroEmacs, xmodem, interactive access
to every TOS/BDOS/BIOS/XBIOS/VDI/AES/LINE-A call, mushroom analysis,
on-line documentation, command completion, interactive command history,
multitasking, 25/40/44/50 line switching, and split-screen scrolling.

It's in John Franco's STarter kit as shareware.

Has anyone had any experience with SEDT, Anker Berg-Sonne's EDT-like editor for VAX/VMS, DEC Rainbows, and the Atari ST? Testimonials? I have really appreciated this editor on the Rainbow, and have been considering purchasing the ST because the keyboard so much resembles what I'm used to. I would like to know how much more of my environment (that is, editor) I can preserve on the ST.

This has been a sore point with me for some time. ExcUuUse me, but
WHY NOT!? It seems to me that someone asked this several months ago
and the reply was something like "it's too difficult" or something.

How about it gang, is it feasible to write an accessory loader/unloader?
Has it been done? Could anyone upload it if they have written it? Huh,
With such a beast, desk accessories could even become useful!

    I used a SONY monitor with mine, don't have the model number right here, however. That particular model had a switch in the back for both TTL and analog levels. Apparently you can now get dealers to order the non-standard 13 pin connector, but I had to cut the cable for my monochrome and add an adaptor plug.

I can now use the SONY on both my IBM and ST just by switching cables and changing from TTL to analog. No problems excpet no sound from the ST.

One of the criteria the patent office uses (or is supposed to) in granting
a patent is that a modification to an existing device/process cannot be
obvious to a person of usual competence in the field. Perhaps they felt
that it would take unusual competence to figure this one out? (:-)

[Yum ...]

Hi People,
Question time again. I'd appreciate anything anyone could tell me. Please reply directly to me or to the net, whichever you prefer (I think these are questions of reasonably general interest).

1) Hard disks: I'm interested in getting a 20Mb hard disk. I've heard that the Supra hard disk is superior to the Atari hard disk, but I do not know any more. How do the two disks compare in terms of

1) Speed
2) Convenience, ie. size, installation.
3) Compatibility. Someone told me that the reason I should choose the Atari disk is because it will remain 'compatible' over future versions of ROMS, etc. Is the Supra any different? Others have said that the Supra is nicer because it has a longer cable, is smaller, faster etc. Comments?
4) Price. I've heard of a discount offer by Atari to students that'll make their disk available for about $640. How does the Supra disk compare price-wise?

2) Clock cards: I've recently heard of two alternatives to the Logikhron clock cartridge: One is the piece from No Solder Required (the Timesaver) mentioned by Neil Harris, which plugs under the U2 ROM. Has anyone used it? I couldn't get hold of the company, does anyone happen to have a phone number?

The other is the stuff mentioned in Jerry Pournelle's column in last month's BYTE, from Mind Mine. Their card plugs somewhere into the key board, and runs off a pair of Nicads, good for about 7-8 days without powering up the ST. The batteries charge up when the machine is powered up, etc. At $55 (including shipping), its doesn't seem that great a deal; does anyone know if it works well, etc?

3) Neil Harris: I've tried contacting him a couple of times, but I always get a message from 'lll-crg' saying that 'vecpyr' is an unknown host, ie. the message gets as far as lll-crg, then it says

'vecpyr!atari!neil' is unknown. Please let me know if there

is an alternate path to 'atari'.

Well, that's it. Thanks in advance for your comments. If I get enough letters on a subject, I'll summarise to the net.

> if the bus error handler is willing to be clever. However, I haven't
> seen any actual code... Anyone know if this is true? If so, what
> are the instructions that can't be restarted?

Probably true. The 68000 is a sort of mutated PDP-11, and software on the 11 could backtrack well enough to restart most instructions. This is what Unix on the 11/40, 34, 23, 60, et al did/does. The major problem comes when an instruction modifies registers: which registers did it modify before it died? The larger 11s had an MMU which would tell you. The cut-down version of the MMU, which is what the 40 et al had/have, won't. So the software has to guess. It can usually guess right. The fundamentally intractable cases are where the instruction modifies the same register more than once, and you can't tell how many times it did it before the fault. The automatic stack growth on small-11 Unixes would generally fail if you used something like "cmp -(sp), -(sp)" to grow the stack two words; I believe the compiler never did this, and assembler

programmers simply had to look out for themselves. On the 68000 it's
worse, because important and useful instructions like move-multiple
can modify the same register several times.

Does anyone know if it would be possible to connect a remote micro computer
to an ST through the DMA "port?" I have a CP/M-68K machine with an RS232
and a PIO connection available and would like to use its 1024K RAM disk and
floppies as additional drives for the ST. The RAM disk would be especially
useful. I thought of using the DMA port because I was sure I could get the
other machine to imitate a diskdrive without the ST's knowing that there is
no disk there. The software on the CP/M side should be easy if I just
treat the ST requests for directories as calls to user areas. It would
need to translate sectors and directory requests from the ST format into
the CP/M format and back.

But I was wondering about signals from the ST ports and what would be
required to make them compatible with another machine. If a DMA <-> RS232
were possible, it shouldn't be too hard to use any machine with an SIO as a
remote. If the DMA plan would not work, what other ports, besides the
ST serial line, might be used? I need the serial line for the modem. Would
a RAM disk driver work as a model for an ST resident program to treat one of
the ST ports as a disk? Then the program on the other end could handle the
sectoring and finding the files.

The _other_ DMA connector in the IBM emulator.

> Does the approx. $300 for the emulator include a 5-1/4" drive?

No, it just includes a connector for one. The drives are widely available
for so little money that it wasn't worth it for us to put one in.

  [Waka - Waka - Waka - Waka]

   On Monday Aug 18th Leonard Tramiel spoke at a meeting of the
Boeing Employees Computer Society. I am not an Atari owner, but
I attended just to see what was there. He said many things that
seemed too good to be true about coming Atari hardware.
   The following is my impression gathered from him and talk with
other hackers at the meeting:
   The next major product to be released is the TT. It is a 68020
based UN*X box with 68881 floating point support and memory managed
multiprocessing. It will have no graphics capability. It will have
eight DMA ports which can be connected to peripherals such as disk
drives or STs. It was not clear whether the memory management will
use the 68000 series chip or not, but will probably support virtual
operations. I have no idea of the eventual cost of such a box, but

cheap UNIX boxes are currently all over $8k. For about $2k from Atari, a crunch unit would be a major coup. The actual announcement at COMDEX should settle that. I wonder how much RAM it has 2M? 4M?

The implications are that a multi-user, multi-terminal UNIX system with hard disks and bit mapped graphics terminals capable of running a window for each of several processes will be possible.

Another product mentioned was the successor to the 1040ST. I will call it the 2080ST for convenience. It is reasonable to expect that it will have 2Meg of RAM. The relevant quote on graphics was: "With the same resolution as the current hi res mode (640x400) it will have as many colors as the current lo res mode". The current low res mode has 16 colors, which requires four bits per pixel. This implies that if the 2080 has a hi res mode with one color per pixel (monochrome) it would have twice the resolution i.e. 1280 by 800. This is in the class of engineering workstations like Sun, Apollo, and MicroVAX.

Tramiel confirmed that the 2080, due for release probably near Xmas will have a custom blitter chip. This should greatly increase the speed of graphics operations. It would still have a 68000 for cpu.

He denied that Atari would ever produce a 1024 by 1024 display. This is probably because it is tough to make those numbers come out even. He also implied that the 2080 would not have a separate keyboard but I am not sure about this.

I am particularly impressed with the Atari approach to expansion because it permits owners of STs to keep them and still upgrade to the power of a 32bit cpu with a real operating system. The STs become intelligent terminals. If much of this is true, the Atari system will be a definite competitor for the Apple Unix machine (Jonathan?) rumored to be announced in April.

I hope I haven't stepped on anybody's toes,
Chas.

{
     register int  j;
     j = (97 * n) / 12345;   /* integer result, long intermediate
     */
}
main()
{
     register long i;
     for (i=0; i<0x20000; i++) {
          subr();
          if ((i&0xFFF) == 0)
               printf("t = %lx\n", i);
     }
}
------------------------------------------------
```

The reason is that subr() is compiled into: (excerpt)

```
     MOVE D7,-(A7)  /* save the "register int j" space,        */
     MOVE.L    #97,D7        /*  but use it as "register long scratch", */
                    /*  upper word of main's i gets clobbered! */
     ...
```

(If you declare > 1 register, MOVEM.L ,-(A7) is used, so no problem.)
This is especially surprising because in MOST other cases the compiler
moves register vars into a scratch register (D0) before doing ANYTHING
with them, which is a waste of time and space. For example:

```
     register int  i, k;
     i = i + k;
```

compiles into (even if mmimp'roved):

```
     MOVE D7,D0
     ADD  D6,D0
     MOVE D0,D7
```

You would think that that's because while evaluating "i + k", the
stupid compiler doesn't know yet that it is not going to keep the old
value of i, i.e. it could say "j = i + k". But look:

```
     register int  i, j, k;
     i = j + k;
```

compiles into:

```
     MOVE D6,D7
     ADD  D5,D7
```

- i.e. in the former example the compiler is not stupid, just lazy!

Anybody at Megamax listening?

Disclaimer: Although I AM disappointed that I have to spend so much time debugging a compiler I spent $200 on (and get no rebate...), I still think that the Megamax compiler is the best we have right now. But, if anybody has had experience with the brand new Mark Williams compiler/shell, please let us know! (bug density, speed of compilation, quality of code...)
At something like $125 for compiler AND shell it MIGHT be a bargain, unless you have already spent your money on such things. But then, the compiler output products might work with the shell's I/O redirection...

- Moshe Braner

Corson Hall, Cornell U., Ithaca NY 14853   607-272-3487

.!*************************************************************************
.Chapter 1 Introduction
.PP
$Name is a program that emulates most of the functions of DEC's
(Digital Equipment Corporation) VT102 text terminal and the vector mode
of Tektronic's 4014
graphics terminal. The program and its documentation can be copied,
distributed and used free of
cost, but may not be sold for commercial purposes. Please contact me, if
you
find bugs or have suggestions for revised versions of $Name, but read
appendix A
and the implementation notes first.
.PP
Some compromises have been made in the implementation of the VT100
```

```
special graphics
character set and double height/width characters, but as soon as we can
design and load fonts on the
ST, this will be fixed. Other things which are planned for future
releases:
.nf
.in 10
.sp 1
-Tektronix 4105 commands (already started!)
.br
-VT200/VT220/VT132 compatibility
.br
-sideways scrolling for 132 columns
.br
-backwards scrolling
.br
-desk accessory version (for use with GEM-Kermit)
.br
-make $Name work with the blitter-chip
.br
-speedup the redrawing of vectors
.br
-saving of vectors to a GEM metafile
.br
-color version (just need a color monitor to try it out)
.sp 1
.fi
.br
.sp 1
GEM is a trademark of Digital Research Co.
.br
DEC,VT are trademarks of Digital Equipment Co.
.br
Tektronix is a trademark of Tektronix Co.
.br
Atari is a trademark of Atari Co.

.!*********************************************************************
.Chapter 2 Starting using $Name
.SH Requirements
To use $Name you need:
.in +5
a ATARI ST computer
.br
a monochrome monitor (color compatibility is not verified yet)
.br
a RS232 standard cable
.br
a computer to talk to
```

```
.br
a floppy disk with ${Name}.PRG on it
.in -5
.SH Getting started
After connecting your ST to your host computer, double click the
$Name Icon. After the program has been loaded you will (hopefully) see
the $Name opening dialog. Now you can select the size of the
vector/filecapture
buffer, if you select 0 or a size to big for your free RAM no
buffer will be allocated.
.PP
Probably now a alert box will appear, press <Return> (in this manual
<xx> means
the key with xx on it) and ignore the warning ($Name didn't
find the file DEFAULT.SET, we will create it later on), the screen
will clear to white (on a monochrome monitor) with a status line on line
25.
Press <Help> and the  $Name selection dialog will appear, the actions
which
you can select are:
.in +5
.bd
.sp 1
Save Setup
.br
Save a setup file to disk
.sp 1
.bd
.br
Load Setup
.br
Load a setup file from disk
.sp 1
.bd
.br
Edit F-Keys
.br
Assign a string to the function keys
.sp 1
.bd
.br
Set Terminal Parameters 1
.br
and
.br
.bd
Set Terminal Parameters 2
.br
allow you to set the parameters of the serial port and the terminal
emulator
.sp 1
.bd
File Transfer Parameters
```

```
.br
Allows you to set the parameters for ASCII file transfer
.sp 1
.ne 2
.bd
.br
A little bit of help
.br
Gives you some help on the functions of the special keys
.sp 1
.ne 2
.bd
Leave Menu
.br
Leave this dialog and return to terminal mode
.in -5
.sp 1
Click the box |Set terminal parameters 1| (|xx| means a GEM button with
the
text xx in it) and a new dialog will appear.
Selecting the different values for the parameters is quite straightforward,
just click on the buttons with the right values (we hope you know them,
otherwise you will just have to experiment) and when you are finished
select |OK|. Now you are back in the main dialog, to save the setup select
|Save setup|, a normal GEM file selector dialog will appear, if you want
to
use this setup as default save it with the name 'DEFAULT.SET' and $Name
will
load it automatically on startup. To leave the main dialog press <Return>
or
select |Leave Menu|.
.PP
If you have adjusted the parameters correctly, you should now be able to
communicate
with your host computer. Some operating systems (VMS) try to identify
the terminal automatically, depending on your setup $Name will
identify itself as a DEC VT102 or VT100. A VT102 has more 'advanced'
editing functions (which results in less overhead in transmitting inserts
etc.) so leave this
option on VT102 if possible. If you have to enter the terminal type
manually try VT102 first (changing from VT102 to VT100 only changes the
report from $Name,
not the actual commands $Name understands).
.SH Exiting $Name
To stop $Name press <Undo>, if there is nothing in the buffer you will be
returned straight away to the Desktop, otherwise a alertbox will appear
asking for confirmation.
.SH Vector graphics mode
After receiveing the control code 'GS' or the 4105 command 'ESC'%!0
(ASCII control characters are enclosed
in apostrophes to distinguish them from printable characters, a space is
 written 'SP') from the host, $Name switches to a
separate graphics screen, if the host doesn't send 'ESC''FF' (the ASCII
```

characters
Escape and Formfeed) before
starting a new picture, you will have to clear the screen manually with
<Alt><F1>. The incoming characters will be interpreted
as Tektronix encoded vectors or commands (see appendix A) until $Name receives
one of the following codes:
.in 5
.sp 1
'CR' or 'US' will return you to VT102 mode if the first 'GS' was
received there,
otherwise the terminal will enter Tektronix alpha mode.
.br
'ESC''FF' will clear the screen and enter Tektronix alpha mode.
.br
'ESC'%!1 will return to VT102 mode.
.in 0
.sp 1
On returning from Tektronix to VT102/VT100 mode $Name only switches the
logical screen (the one on which output operations are performed) back to
the text mode screen. To switch
the physical screen (the one you actually see) back to the text screen,
press <Alt><F6> (this key combination always returns you back to VT102/VT100
mode!). To view
your picture again press <Alt><F5>.
.SH Zoom mode
If you selected a vector buffer larger than zero kilo bytes, you can
redraw a picture with different scaling factors. To select this mode press
<Alternate><F9>, the screen will be cleared, the current contents of
the buffer will be drawn on the screen and the normal arrow mouse cursor
will appear.
.PP
To select the region of the picture you want to magnify, move
the arrow to the upper left corner of the region, press the left mouse button
and drag the mouse to the lower right corner of the region (a 'rubber box'
should follow the arrow) and release the button. The resulting picture will
be scaled so that the larger side of box will fit on the screen (if the option
|True Aspect| is selected). You can repeat this operation till a magnification
factor of thirty is reached.
.PP
 <Backspace> will restore the previous scaling
factors, the arrow keys will move the screen a 10th of the screen
width/height
in their direction and <Return> will leave zoom mode (all other keys only
redraw the screen). Remember that if your picture is built out a lot of vectors,
the redrawing may take some time!
.SH GIN mode
The sequences 'ESC''SUB' will enter GIN mode from any of the Tektronix modes,
it will not work from the VT102/VT100 mode since SUB cancels any ANSI command.
A crosshair cursor will appear which can be moved with the mouse. Pressing
any key on the keyboard will cause a GIN report to be sent to the host and
exits the GIN mode to Tektronix alpha mode. Moving the cursor to regions of
the screen with invalid coordinates will cause an invalid report (if you have
selected |True Aspect| the 1024*780 (4096*3120) Tektronix coordinate system is

mapped to a centered region sized 525*400 pixels on the ST monochrome screen).
.SH Tektronix 4014 alpha mode
This mode is only included for compatibility with the GIN-mode and is not very usefull.
But you can position alphatext anywhere on the screen. This mode will probably be replaced in future versions with a 4105 compatible alphamode.
.SH Using the special keys
Here is a list of the functions on the special keys (press <Alternate> and the key listed here):
.sp 1
.in 5
<F1>
.br
Erases the graphics screen from any terminal mode.
.sp 1
<F2>
.br
Toggles the foreground/background color (white on black or
black on white).
.sp 1
.ne 2
<F3>
.br
Toggles between blinking and static cursor.
.sp 1
.ne 2
<F4>
.br
Prints the contents of the textbuffer.
.sp 1
.ne 2
<F5>
.br
Switches the physical screen (the one you see) to the graphics screen.
.sp 1
.ne 2
<F6>
.br
Switches the screen and the terminal to VT102/VT100 mode.
.sp 1
.ne 2
<F7>
.br
Resets the terminal, reads the default values from disk.
.sp 1
.ne 2
<F8>
.br
Toggle autoprint.
.sp 1
.ne 2
<F9>
.br

```
Enter zoommode.
.sp 1
.ne 2
<F10>
.br
Reset the Tektronix mode.
.sp 1
.ne 2
<B>
.br
Send a short break (0.233 s).
.sp 1
.ne 2
<L>
.br
Send a long break (3.5 s).
.sp 1
.ne 2
<A>
.br
Send the answerback string
.sp 1
.ne 2
<W>
.br
Switch to 132 column mode (really only 128*64).
.sp 1
.ne 2
<S>
.br
Switch to 80 column mode.
.sp 1
.ne 2
<X>
.br
Reset the XOff flags of the bios.
.sp 1
.ne 2
<C>
.br
Start/stop file capture.
.sp 1
.ne 2
<R>
.br
Playback a captured file.
.sp 1
.ne 2
<T>
.br
Start ASCII file transfer.
.sp 1
.ne 2
```

```
<Help>
.br
Atari screen dump.
.sp 1
.ne 2
<P>
.br
Atari screen dump of the physical screen.
.sp 1
.ne 2
<Insert>
.br
Start the single line editor.
.in 0

.!*  File: CHAPTER3.PRF                                               *
.!*                                                                   *
.!*********************************************************************
.Chapter 3 More about $Name
.SH Terminal Parameters 1
To change these settings, press <Help> and select
.br
.ce
.bd
 |Change Terminal Parameters 1|
Following parameters can be changed:
.in 5
.sp 1
.bd
Baud
.br
Selects the rate for the serial port.
.sp 1
.bd
Flowcontrol
.br
Selects the flowcontrol mode, these functions are implemented by the bios.
.sp 1
.bd
Parity
.br
Selects the parity mode, these modes are implemented by the bios.
.sp 1
.bd
Data/Stop
.br
Allows you to select the number of data and stop bits, implemented by the bios
.sp 1
.bd
Mode
.br
```

Allows you to put the terminal in one of following modes:
.br
Full: Data typed on the terminal is echoed by the host computer.
.br
Echo: $Name echos user input on the screen.
.br
Local: User input is only sent to the screen.
.sp 1
.bd
Terminal
.br
Selects the terminal mode and change the terminal identification.
4014 selects
4014 alpha mode!
.sp 1
.bd
Attributes
.br
Allows you to change the processing of text attributes:
.br
Ignore: All attributes except inverse are ignored, the terminal identifies
itself as if it had the advanced video option (AVO), this is the quickest
output mode.
.br
AVO: The terminal process all DEC text attribute codes, slowest mode.
.br
NoAVO: The terminal only processes underline and inverse attributes.
.sp 1
.bd
Scroll
.br
Selects between slow and quick scroll.
.sp 1
.bd
Aspect
.br
This option controls the scaling of pictures.
.in 0
.SH Terminal Parameters 2
To change these settings, press <Help> and select
.br
.ti 5
.bd
.ce
|Change Terminal Parameters 2|
following parameters can be changed:
.in 5
.sp 1
.bd
GIN Termination Sequence
.br
Determines the string sent after a GIN or status report.
.sp 1

```
.bd
Answerback
.br
The string which is sent as answerback message.
.sp 1
.bd
Print terminator
.br
Determines if a FF is sent after each print operation or not.
.sp 1
.bd
Printer
.br
Determines if a printer is connected or not.
.in 0
.SH File Transfer Parameters
To change these settings, press <Help> and select
.br
.ti 5
.bd
.ce
|File Transfer Parameters|
following parameters can be changed:
.in 5
.sp 1
.bd
Start of file transfer
.br
A string that is sent before file transfer starts.
.sp 1
.bd
End of file transfer
.br
A string that is sent when the transfer finishes.
.sp 1
.bd
Delay after every character [ms]
.br
Sets the time $Name waits after every character sent (this is implemented
with the AES call event_multi, this means the 200Hz system clock is used).
.sp 1
.bd
Method
.br
If Paced by Echo is selected, $Name waits for every character sent to be
echoed (except ASCII control codes), doesn't time out!.
.sp 1
.bd
Send EOL as
.br
Selects if 'CR''LF' is sent as 'CR''LF','CR','LF' or 'SP''CR'.
.SH Setup Files
Follow information is stored in the setup files:
```

.br
.nf
.nj
.in +5
Version Number
Baud
Flowcontrol
Parity
Databits
Stopbits
Communication Mode
Terminal Mode
Attribute Mode
Scroll Mode
Aspect Mode
GIN Termination String
Answerback String
Print Terminator
Printer Mode
Cursor Mode
Screen Mode
ASCII File Transfer Start String
ASCII File Transfer Finish
ASCII File Transfer Delay Time
ASCII File Transfer Method
ASCII File Transfer EOL Type
Function Key Strings
.in 0
.ju
.fi
.sp 1
Loading a setup file from a different version of $Name will result in
a version conflict error message.
.SH File Capture/Playback
These functions were only added for debugging purposes, but can be used
for simple seven-bit ASCII file capture and for playing back a sequence
of terminal commands (redrawing a picture as well).
.SH Editing Function Keys
To edit the string assigned to a function key, press <Help> and select
.br
.ce
.bd
 |Edit F-Keys|
.br
you now can edit the strings, the cursor keys will move you to the string
you want to edit, <Esc> will clear the string, <Backspace> will delete to
the left, <Delete> the current character. Control codes can be entered by
pressing <Control> and the appropriate key (see appendix B).
.SH The Statusline
The 25th line on the screen is used as a statusline in VT102/VT100 mode
it should look like this:
.sp 1
.bd

```
.nj
.nf
$Name $Version                                          R 1234
.sp 1
.fi
.ju
1234 simulate the LED's on a VT100, when they are set they will change from
inverse to normal. R indicates that the terminal is in replace mode, an I
insert mode.
Other indicators: C file capture is on, L the keyboard is locked.
.SH The Single-Line Editor
To make working on systems that don't have a single-line editor (short
sle) easier, a simple
sle is implemented in $Name. The last 10 lines typed by the user are
stored in a circular buffer. Pressing <Insert> starts the sle, the status line
will clear and the current line will be displayed instead. Following
functions are provided:
.br
.in 5
Left and right cursor keys: move the cursor one character left or right.
.br
Up and down cursor keys: display the next or last line in the buffer.
.br
<Delete>: delete the character under the cursor.
.br
<Backspace>: delete the character to the left of the cursor.
.br
<Insert>: abort the sle.
.br
<Return>: send the line and leave the sle.
.in 0
The sle is always in insert mode.
.SH ASCII File Transfer
<Alternate><C> will capture all ASCII characters sent to $Name in a file,
this option disables zooming of pictures. You can play back the contents
of a File with <Alternate><R>, the characters are processed as if they were
received from the serial port.
.PP
Pressing <Alternate><T> will send a file to the host using the current
file transfer parameters. <A> will abort the file transfer.
---cut here---
.!*********************************************************************

.!*********************************************************************
.Chapter 4 Implementation Notes
.SH General
Most of $Name is written in CCD/OSS Pascal and uses standard
GEM,GEMDos,Bios and XBios calls. The exceptions are:
.br
.sp 1
.in 5
```

Scrolling up, this is done with a assembler routine instead of a raster
operations.
.sp 1
Peeking and poking in user and supervisor status is done in assembler.
.sp 1
.in 0
In future versions probably more will be done in assembler.
The Bios input buffer for the serial port is expanded to 2000 bytes. If
no attributes
except reverse are set and the character cell height is 16 or 8 pixels, screen
output is done with the Bios call BConout (Bios 3), this is at least twice as
fast as using GEMDos and three and half times faster than using GEM.
Typical times (may change
from version to version, these were taken with Beta version 0.7):
.sp 1
.in 5
.nj
.nf
Polling of the serial port and keyboard (main loop): 0.65ms
                                        (Beta V1.2   0.48ms)
(if ther are characters in the input buffer, a maximum
of 20 are processed before the keyboard is polled again)
The following data was measured with simulated input
to the VT102 command processing routine, the times
are per operation:
   Carriage return   0.6ms
   Clear complete screen ('ESC'[2K):   140 ms
   Clear complete line ('ESC'[2J):   10.0ms
   Absolute cursor address combination
   ('ESC'[H'ESC'[10;10H):   5.6ms
   Linefeed with scroll: 30.0ms
   40'000 characters 8 per line   4.4ms
                     80 per line   1.0ms
                                         (Beta V1.2   0.88ms)
   4'000 characters bold (highlighted)
                     80 per line   3.5ms
.sp 1
.in 0
.fi
.ju
To decode one character without any output operation (moving of cursor
etc.) takes less than 0.5 ms. Use of $Name at 9600 baud is probably
not unresonable, but it may need flowcontrol.
.PP
The carrier detect signal and the break bit on the Mfp are polled once per
main loop and if they are present a appropriate message is displayed.
.SH VT102/VT100 Mode
.SSH 132 Column Mode
A simulation of 132 column mode is done using the 6*6 font. The characters
are spaced in 5 pixels increments instead of 6, this gives (monochrome)
128 columns * 64 lines. Characters between 128 and 132 columns are lost.
This mode will probably be exchanged for sideways scrolling later. Restrictions:
No double height/width characters.

.SSH Special Graphics/Line Drawing Character Set
The line drawing characters are mapped to lines (which are actually drawn)
and to the '+' and '|' characters. The other special characters are mapped
as good as possible to the ATARI ST character set. Hopefully this will change
before the end of year, as soon as we can design and load fonts this will be
done properly.
.SSH Double Height/Width Characters
Restrictions: only USASCII set, no double height in color. The same goes here
as for the line drawing set.
.SSH HDS200 International Character Set
Undocumented, only for use at CHRZU1A.
.SH Tektronix Mode
.SSH General
The Tektronix mode is still a bit in a mess. This will change with the
using the 4105 command set, this implies that you should only use the
vector mode of the 4010 emulation as all other 4010 commands will probably
be removed from the program.
.PP
Right now scaling is done with respect to a 4010 with 1024*780 points, this
probably will change for the 4105 (512*360) emulation. In Tek coordinates the
screen measures 4096*3120 points (4105: 4096*3072 points).
.PP
For redrawing and zooming purposes the incoming characters are stored in
a linear buffer. This is quite a memory saving way to store them, but on the
other hand this means they have to be decoded every time the vectors are drawn.
.SSH Alpha Mode
Restrictions: 1 margin, all (well nearly all) character sizes are the same
only the spacing is different.
.SSH Vector Mode
.sp 1
.SSH Zoom Mode
Restrictions: No zooming of graph text, slow.
.SH Problems
Sometimes the serial port seems to blocked (this has happened to me with
other ST terminal emulators aswell), possibly we received a XOFF but
no XON. Pressing <Alternate><X> wil reset the XOFF flags of the bios.
.PP
Don't use the |Change Terminal Parameters 1| dialog in an editor or the like,
for some mysterious reason the serial port outputs a delete character if
you
actually change something and exit with |OK|.
.SH The German keyboard and other horrible things
Due to the way the keyboard interrupt routine is written for the German
bios
not all of the control codes can be produced with the keyboard. To make
local
debugging easier <Alternate><V> will send a 'GS' code and to allow you
to get to
the [,],{,},@, and \ characters without pressing two to three keys the
umlauts
are caught and replaced by the ASCII characters on the keys (if somebody
sends
me the layout of the other none US keyboards I will try to do the same

thing).
Do not count on this feature to stay, maybe this will be replaced by
loading
a keyboard table.

---cut here---

.!*************************************************************************
.AP A Control Codes and Escape Sequences
.fi
.ju
.PP
This appendix list control codes and escape sequences that
complete implementations of VT102 and Tektronix 4014/4105 terminals should
interpret and the functions they should initiate. * marks functions that
are redundant or not possible on an Atari ST computer, *NI marks other not
implemented functions (due to my laziness?), *RI uncomplete implementation of
a function, please read the implementation notes for details.
.PP
Consult the ASCII table for numeric values of the control codes, 'Ps',
'Pn', 'Pc'
and 'Pl' denote decimal values (Esc[10;10f postion cursor at text coordinates
(10,10)).
.PP
The following control codes and commands, the syntax and the command
interfaces as a whole
could possibly be patented or/and copyrighted,
please consider this list as 'for information only'. Commercial use is strictly
forbidden.

Kermit SHOULDN'T need anything special to run. I have two versions of
Kermit (A GEM version and the developer's kit version) and both perform
perfectly with the AVATEX 1200. I upload and download to/from a vax
running UNIX 4.2BSD over PacBell lines. Packets are sent/received
with no retries or errors.

The problem MAY be the noisy lines to work that you mentioned. The AVATEX
is slightly less friendly in noisey environments than the Hayes. But, at
the price of each, the Avatex has my full support.

This had to happen: after finishing sending the files for UniTerm yesterday, I did some work with EasyDraw, after an hour or so I started UniTerm and it crashed! The problem is due to the GDOS which is disributed with EasyDraw, at least one of the functions of CCD/OSS Pascal doesn't seem to work and a VDI-call returns 0 as height of a character, maybe all these problems are my own fault or are due to the prerelease version of GDOS. So for now: don't try to run UniTerm with GDOS loaded! This will be fixed a.s.a.p., if anybody has had the same problems please contact me.

I don't quite buy that. Look at the #1 business machine -- what kind of MMU
does it have? The Atari has just about the same features as the IBM PC --
including lack of reasonable system software. The Amiga at least made an
attempt to make up for the lack of an MMU with good system software.

Please consider this version of UniTerm as a Beta test version, some functions
are not very well tested, but the VT102 mode should be OK.

To cut down the size of the uuencoded executable I had to cut it in three
pieces, the files should be in part 3,4 and 5 of this posting. At the end
of each line except the 'begin' and 'end' lines there is a lower case a,b
or c, this is to stop trailing blanks being destroyed by Bitnet/Earn. To
uudecode Uniterm cut away the headers from files 3,4 and 5 and concatenate
them in some way. The first part should have a's as line endings the second
b's and the third c's. Now you should be able to run the resulting file
through uudecode (if it doesn't work try deleting all lower case
a's,b's and c's), name the resulting file UniTerm.Prg.

```
      File sizes: Part a : 48379 Bytes
                       b : 44800 Bytes
                       c : 46277 Bytes
                   Total  :139456 Bytes
                UniTerm.Prg : 96522 Bytes (this is one Byte less than the
                                           original file, probaly a bug
                                           in my version of uuencode, but
                                           it still seems to work)
The manual for UniTerm is in PROFF source in file 2 of this posting, to
cut it up in to the seperate files search for the string
---cut here---
you should end up with following files:
                ug.prf
                macros.prf
                toc.prf
                chapter1.prf
                chapter2.prf
                chapter3.prf
                chapter4.prf
                apndx1.prf
                apndx2.prf
                apndx3.prf
Run ug.prf thru PROFF and you should have the UniTerm user's guide. If anybody
doesn't have PROFF I might send them the formatted manual. The macros were
adopted from those used for Tim Oren's ProGEM series, thanks to who ever wrote
them.

Please send me bug reports and suggestions concerning UniTerm, I will support
it and will release a new version in 2 to 3 months.

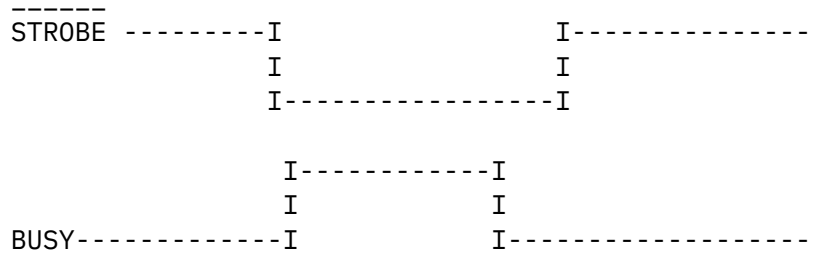
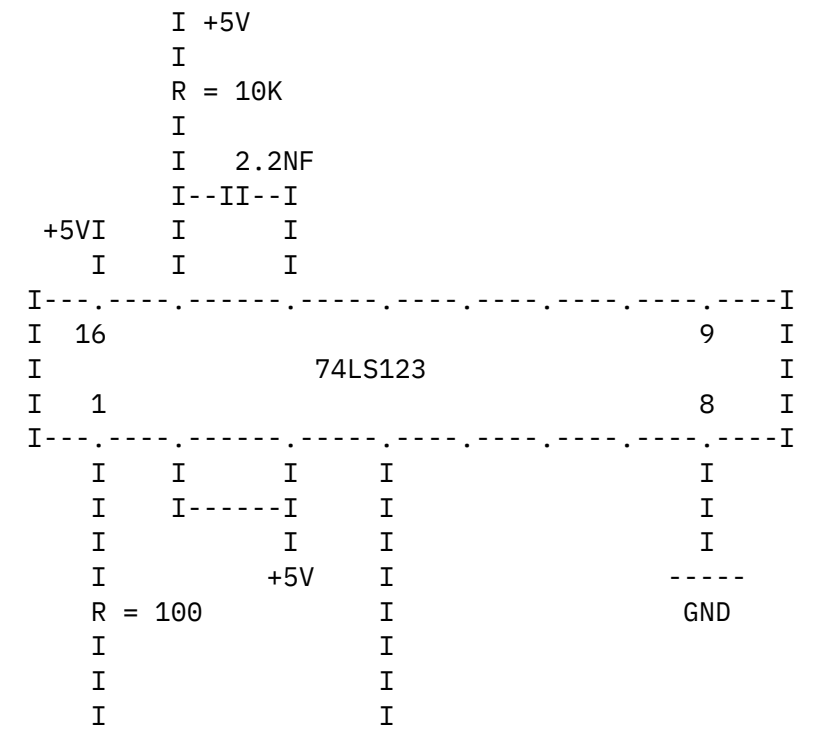
DEER JAN,

THE PROBLEM OF THE DDOOUUBBLLEEDD CHARACTERS LIES IN THE STROBE
PIN NUMBER 1 THAT GOES TO THE PRINTER. THE PULSE IS TO LONG SO
AFTER THAT THE BUSY-LINE HAS DROPPED THERE IS STILL A STROBE PULSE
AND THE CHARACTER WILL BE PRINTED AGAIN.



INTERUPT THE STROBE LINE AND PUT THE FOLLOWING SCHEME BETWEEN IT
THEN THE PROBLEM HAS TO BE SOLVED.



```
  STROBE IN        STROBE OUT
FROM COMPUTER      TO PRINTER
```

```

Summary: Nice, but expensive.

[]

The same chip (or whatever you would call this thing) apparently is sold
by JADE, but is called the "no-slot-clock" and is directed towards the IBM
PC. "Installs easily in the motherboard or option boards of any computer
with a 28-pin PROM socket", they say.  No word on software.  Price: $49.
Personally, I'd wait till is comes closer to the price of a clock chip
and a pair of batteries added up.

I also think it's kinda' funny that the solution for a computer with 2 clocks
is a third one.  Are you folks at Atari going to have a perrenial clock in
some future model?

> Lattice C gemdos bindings...

    First you must use another flag in fattrib to scan for folders.
    Lattice C expects allways 32 bit integers as arguments, but
    the gemdos, bios and xbios functions keep some sort of
    conversion table to make shure that all parameters are of the
    required size.

I. Problems with OSS/CCD Pascal and preliminary version of GDOS

None of the calls to VDI (like clear_screen) seem to work, so no fixing of this problem (or am I doing something wrong?).

II. Bugs in UniTerm

Sorry, but 2 bugs crept in to UniTerm going from version 1.1 to 1.2:
Carrier Dectect doesn't work.
Delete ($7F) is not ignored, but is displayed as a small triangle, this is a serious problem if your host computer sends Delete as a padding character.

If you really want a fixed version, I will send it to you (I would rather not post the three uuencoded files again).
Anybody on cernvax should be able to get UniTerm from Michael Doser (ASTERIX group).

Simon Poole.

>When I accidently hit two keys at the same time on my 1040ST, while
>using the VT52 emulator desk accessory, the serial port sometimes locks up.

I found the Atari VT52 emulator (on my 520ST) can lock up. In my case it
was triggered by RTS/CTS problems. My own terminal emulator did not lock up
under the same conditions, and printed a warning that the RS232 port was
not ready to transmit data.

I guess the Atari emulator does not do an "bcostat" bios call before doing
the "bconout" call. No way for a user to fix, but trivial for the writer
of the emulator to fix, at least to the extent of not locking up. Unjamming
the port may be harder. I power cycled.

Anyone care to tell me what system call or calls are necessary to reset the
RS232 port? In my case I found that toggling the RTS/CTS option, or changing
the baud rate, with the "rsconf" xbios call was not sufficient.

> timing is *so* critical that running the address lines through a
> 35ns RAM would result in missing RAS and/or CAS windows on the
> DRAMs. Bad things happen.

By design, this can be a non-problem. Drams have three parts to each cycle:

   1) RAS/CAS precharge   -- Overlapped with end/begining of M68k cycle
   2) RAS/Row address   -- taken from M68k address lines after AS asserted
   3) CAS/Col address   -- taken from MMU result after delay from AS asserted

The delay from RAS to CAS required/accepted by most DRAMS is about the same is running the address lines thru a mapping ram or adder/comparator based mmu. Addresses and function codes precede AS by half a clock giving a little more head room. RAS can be started without knowing if the translation will be valid, since witholding CAS is a refresh cycle.

>
> The other gotcha is that by the time the lookup RAM can indicate
> if a location should generate a bus error, the memory controller
> is already comitted to the read or write cycle. You'd have to
> map every unused page to some piece of scratch RAM.

Using a mapping ram, two of the outputs are valid and write-protect allowing:

```
RAS  := AS2RAS_DELAY  * AS

DTACK:= AS2RAS_DELAY  * AS * MEM_ACCESS                          +
        ROM_DELAY     * AS * ROM_ACCESS                          +
        IO_DELAY      * AS * IO_DTACK

CAS  := RAS2CAS_DELAY * AS * MEM_ACCESS *  VALID *  RW           +
        RAS2CAS_DELAY * AS * MEM_ACCESS *  VALID * /RW *  WPROT

BERR := RAS2CAS_DELAY * AS * MEM_ACCESS * /VALID                 +
        RAS2CAS_DELAY * AS * MEM_ACCESS *        *  RW * /WPROT
```

NOTE: the delay terms can be external (delay lines??) or state terms from on-chip counter/sequencer outputs.

Since you can determine a fault at CAS time, CAS is withheld to prevent writing. DTACK is given early, and BERR asserted on a fault. Target data is protected during the fault for both reads and writes.

It can't be done that way???? We currently run 16mhz 4-CLK memory cycles using 120ns DRAMS and a $15.00 mapping ram based mmu (4-CLK cycles are zero wait state for the M68000, and 1 wait state for the M68020 which uses 3-CLK memory cycles). Stop by next month and we will show you our M68020 UNIX SBC running 3-CLK memory cycles at 16mhz with our mapping ram mmu and 80ns DRAMS. Still not convinced, order now and we will save one from the October build for you to try yourself (starting from $1,800 + tax and shipping).

For a 8mhz M68000 the above the timings are all a piece of cake, including

cycle-stealing arbitration for display accesses.

>
> We looked at this many months ago, and went a different route....

MMU's are left out of toy computers because toy engineers don't know how
to design real computers -- NOT because they take to much time (the above
solves that problem) or because they cost too much (two mapping rams cost
less than $10 in volume, and the rest of the circuit could have been dumped
into the custom parts or pals already on the board -- an adder/comparator
design could have been placed in the custom parts for nearly zero additional
production cost). Ditto for memory parity.

MMU's are also left out of toy computers because toy programmers don't know
how to use an mmu, because toy marketing/sales don't care, and many toy buyers
don't care. If you want a toy computer buy one, I like my toy Mac, I can even
do some real work on it ... the cost of ownership could have been lower though
if less development time had been spent by it's programmers fighting the
memory manager and lack of process/os protection from software faults. With
an mmu, certain failures can be identified much earlier, allowing the product
to mature faster and reach market sooner and possibly stay on the market longer
by supporting CLEAN multiuser/multitasking ... thus being more profitable in
the LONG RUN. MMU's are left out of systems due to short term thinking.

In article <1310@watdragon.UUCP> you write:

>I just bought a db25->centronics connector to hook up my ST to an old
>Seikosha GP-100A printer
>Unfortunately, characters sent from the ST arrive ddoouubblleedd at the
>printer.

I have also experienced this problem and determined that it was due to
a difference in potential between the ground at the connector of the atari
and that of the printer. This causes noise on the signal lines and produces
the effect you mention. A temporary solution is to ensure that one of the
two cable ends is NOT connected to the chasis ground. This problem may stem
from the fact that your equipment is not properly grounded. Are you certain
that the outlets into which your equipment is plugged are grounded? For
example in my house (built about 30 years ago) I discovered that even though
the wall sockets were the grounded type (presumably installed by some
previous owner) the ground screw was not connected to anything, since
the house was wired with only two conductor cable. I hope this helps.

Pardon a couple questions from a person who still has to borrow a friend's
520ST:

What do the file extensions IMG and TOS mean? What other system extensions are
there?

Is an AUTO folder like an MSDOS machine's AUTOEXEC.BAT file (do commands in
the AUTO folder get executed when the machine is booted)? How do I create an
AUTO folder?

Thanks for any help.

Offhand, I would think that putting it in a bell jar and pulling a vacuum on it would be the safest way. But I would try it on another floppy disk first to make sure that nothing else besides the water boils away!!!

This method is good because it will not use any heat and because it will definitely dry out any water inside the device without having to open it. Does anybody else have any experience with the effects of vacuum on a disk?

Considering how important the data is to you, I would also call the disk manufacturer and ask them if they think vacuum is safe and if they have a better idea.

Two points here, one neither the Atari nor the 8088 based PC try to multitask.
The AT has an MMU built into the '286. Lets not debate this issue yet again
(the last time the consensus was "Multitasking is a lot safer with an MMU,
however with clever system software and reasonably well behaved programs
it is not required.")

just to cloud the issue further, i have found (atleast with
PC/Intercomm) that you must use kermit -i (on the vax) and
kermit-image (on PC/IC) for binary files and kermit on both for text
files, if you mix them in any way the transfer will run but you will
end up with null files or the famed garbage.

~~~~~~~~~~~~~~~~~\ lineater, \~~~~~~~~~~~~~~~~~~~~~~~

The following postings contain the parts of my port of microEmacs 3.7
~~~~~~~~~~~~~~~~~

for the Atari ST, i have more features that i wish to add but this seems to work well enough to be released for beta test. Please remember the meaning of beta test (and my track record with ARC) and do NOT edit your life's work with this. I am also posting the emacs.rc file that i use as an example, but for the sake of the net will not post all of the doc's that go with uE3.7, send me email if you need them and if i get enough requests ill post them also. please don't ask for the source, once i have a stable version they will go the the keeper of 3.7 to be incorporated into the master sources. I have implemented the following:

1. color - in med res you get black, white, yellow, and blue; in high res you get black, white, red, green. blue, cyan, yellow, and magenta. if someone has a scheme to add new colors while in emacs, im all ears

2. key bindings - the special keys are bound to the ascii values of their scancodes, i.e. F1-F10 = FN;-FND, Shifted F1-F10 = FNT-FN], Help = FNb, Undo = FNa, Insert = FNR, Clr = FNG, the arrow keys are FNH, FNP, FNK, and FNM for up, down, left, and right; the left mouse button is FNt and the right is FNu. See emacs.rc for some good examples of how to bind these keys.

3. mouse movement moves the cursor - Q. is this useful or an annoyance ?

4. command execution - ^X! will prompt you for a single program name to be executed via Pexec, arguements may be passed

5. cmode - CMODE will be automatically invoked for any file edited which has an extention of .c, .h, .C, or .H

6. all disk i/o is done thru gemdog, im not sure whether this speeds things up or just clutters up the code

Things yet to be done (but im working at it)

1. use hardware scrolling in each edit window

2. add wildcard matching for searching (Q. is this worth it ? would you use it ?)

3. implement ^X^E (execute make)

4. add super hires mode for b/w (40 lines x 80 char)

please send any bugs or suggestion to me, they are most welcome.

combine all three parts of the postings and uudecode it e.g.

```
cat xaa xab xac > emacs.uue
uudecode emacs.uue > emacs.ttp
```

enjoy!

*** REPLACE THIS LINE WITH YOUR MESSAGE ***

a few caveats, dont forget to strip the lineater line and my
signature out of the files before combining them, when editing
the emacs.rc file be careful, any syntax error will cause emacs
to bomb out, if it does it will leave the cursor in a screwed
up condition. Use the Alt-arrow keys (press Alternate and the
arrow keys at the same time) or reboot the system. of course
reinvoking emacs and exiting normally will fix it too.

the shar file for emacs.rc and emacs.hlp follow

```
#! /bin/sh
# This is a shell archive, meaning:
# 1. Remove everything above the #! /bin/sh line.
# 2. Save the resulting text in a file.
# 3. Execute the file with /bin/sh (not csh) to create:
#    emacs.rc
#    emacs.hlp
```

```

     X^N  Next line          M-N    Front of paragraph
     X^P  Previous line M-P    End of paragraph
     X-------------------------------------------------------------------------
     X=>      (2) DELETING & INSERTING
     X
     X<--             Delete previous character
     X^D or <DELETE>  Delete next character
     X^C or <INSERT>  Insert a space
     XM-<--           Delete previous word
     XM-D             Delete next word
     X^K              Close (delete) to end of line
     X-------------------------------------------------------------------------
     X=>      (2a) MORE DELETING & INSERTING
```

```
X
X<RETURN>   Insert a newline             <TAB>  Advance to next tab stop
X^J         Insert a newline and indent  M-^W   Delete paragraph
X^O         Open (insert) line
X^W         Delete region between mark (set using M-<spacebar>) and cursor
XM-W        Copy region to kill buffer
X^X ^O      Delete blank lines around cursor
X-------------------------------------------------------------------------
X=>      (3) SEARCHING
X
X^S  Search forward from cursor position.
X^R  Reverse search from cursor position.
X^X S    Forward incremental search
X^X R    Reverse incremental search
X<ALT> S  Search for the next occurence of the last string (IBM-PC only)
X<ALT> R  Search for the last occurence of the last string (IBM-PC only)
X-------------------------------------------------------------------------
X=>      (4) REPLACING
X
XM-R   Replace all instances of first typed-in string with second
X          typed-in string.  End each string with ESC.
XM-^R  Replace with query.  Answer with:
X    ^G  cancel              .   exit to entry point
X    !   replace the rest        Y    replace & continue
X    ?   Get a list of options   N   no replacement & continue
X-------------------------------------------------------------------------
X=>      (5) CAPITALIZING & TRANSPOSING
X
XM-U UPPERCASE word
XM-C Capitalize word        ^T   Transpose characters
XM-L lowercase word
X^X ^L   lowercase region
X^X ^U   uppercase region
X^Q  Quote next entry, so that control codes may be entered into text
X-------------------------------------------------------------------------
X=>      (6) REGIONS & THE KILL BUFFER
X
XM-<spacebar> set MARK at current position
X^X ^X        eXchange mark and cursor
X
XA REGION will then be continuously-defined as the area between the mark and
Xthe current cursor position.  The KILL BUFFER is the text which has been
Xmost recently saved or deleted.
X-------------------------------------------------------------------------
X=>      (7) COPYING AND MOVING
X
X^W  Delete (Wipe) region       M-W  copy region to KILL buffer
X^Y  Yankback save buffer at cursor
XGenerally, the procedure for copying or moving text is:
X    1)  Mark a REGION using M-<spacebar> at beginning and cursor at end.
X    2)  Delete it (with ^W) or copy it (with M-W) into the KILL buffer.
X    3)  Move the cursor to the desired location and yank it back (with ^Y).
X-------------------------------------------------------------------------
```

```
X=>      (8) MODES OF OPERATION
X^X M    Add mode in buffer             M-M    Add global mode
X^X ^M   Delete mode in buffer          M-^M   Delete global mode
XOVER         Replaces (overwrites) rather than inserts characters
XWRAP         Turns on word wrap (automatic carraige return).
XVIEW         Allows viewing file without insertion and deletion.
XCMODE        Automatic indenting for C program entry
XEXACT/MAGIC  Changes how search and replace commands work (see next page)
X-------------------------------------------------------------------------
X=>      (9) SEARCH AND REPLACE MODES
X
XEXACT   Uppper/lower case is not ignored in searches
XMAGIC   Regular pattern matching characters are active
X           ?   Matches any one character
X           *   Matches any sequence of characters
X    [EXACT MODE NOT READY YET ---- 6/5/86]
X
X-------------------------------------------------------------------------
X=>      (10) ON-SCREEN FORMATTING
X
X^X F         Set fill column
XMn-<tab>Set tab spacing to n charecters between tabs stops
XM-Q     Format paragraph so that text lies between margins
X^X =         Position report -- displays line number, char count,
X                                  file size and character under cursor
XM-^C         Count words/lines/chars in marked region
X-------------------------------------------------------------------------
X=>      (11) MULTIPLE WINDOWS
X
XMany WINDOWS may be active at once on the screen.  All windows may show
Xdifferent parts of the same buffer, or each may display a different one.
X^X 2    Split the current window in two  ^X O Change to next window
X^X 0    delete current window           ^X P    Change to previous window
X^X 1    delete all other windows        M-^V    Page down next window
X                                   M-^Z Page up other window
X-------------------------------------------------------------------------
X=>      (12) CONTROLLING WINDOWS
X
X^X ^    Enlarge current window   M-<n> ^X W   Resize window to <n> lines
X^X ^Z   Shrink current window
X^X ^N   Move window down
X^X ^P   Move window up
XM-^L    Reposition window
X^L      Refresh the screen
X-------------------------------------------------------------------------
X=>      (13) MULTIPLE BUFFERS
XA BUFFER is a named area containing a document being edited.  Many buffers
Xmay be activated at once.
X^X B    Switch to another buffer.  <CR> = use just-previous buffer
X^X X    Switch to next buffer in buffer list
XM-^N    Change name of current buffer
X^X K    Delete a non-displayed buffer.
X^X ^B   Display buffer directory in a window
```

```
X-------------------------------------------------------------------------
X=>      (14) READING FROM DISK
X
X^X ^F   Find file; read into a new buffer created from filename.
X    (This is the usual way to begin editing a new file.)
X^X ^R   Read file into current buffer, erasing its previous contents.
X    No new buffer will be created.
X^X ^I   Insert file into current buffer at cursor's location.
X^X ^V   Find a file to make current in VIEW mode
X-------------------------------------------------------------------------
X=>      (15) SAVING TO DISK
X
X^X ^S   Save current buffer to disk
X^X ^W   Write current buffer to disk
X^X N    Change file name of current buffer
XM-Z Write out all changed buffers and exit MicroEMACS
X
X
X-------------------------------------------------------------------------
X=>      (16) ACCESSING THE OPERATING SYSTEM
X
X^X !    Send one command to the operating system and return
X^X @    Pipe DOS command results to buffer
X^X #    Filter buffer through DOS filter program
X^X C    Start a new command processor under MicroEMACS
X^X D    Suspend MicroEMACS into the background (UNIX BSD4.2 only)
X^X ^C   Exit MicroEMACS
X-------------------------------------------------------------------------
X=>      (17) KEY BINDINGS AND COMMANDS
X
XM-K Bind a key to a command
XM-^K    Unbind a key from a command
X^X ?    Describe command bound to a key
XM-X Execute a named (and possibly unbound) command
X{Describe-bindings}
X    Display a list of all commands and key bindings to a buffer
X-------------------------------------------------------------------------
X=>      (18) COMMAND EXECUTION
XCommands can be specified as command lines in the form:
X    <optional repeat count> {command-name} <optional arguments>
X{Execute-command-line} execute a typed in command line
X{Execute-buffer}  executes commands lines in a buffer
X{Execute-file}        executes command lines from a file
X{clear-message-line}  clears the message line during execution
X   M-~            clears the change flag for a buffer
X-------------------------------------------------------------------------
X=>      (19) MACRO EXECUTION
X
X^X (    Start recording keyboard macro
X^X )    Stop recording keyboard macro
X^X E    Execute keyboard macro
XM-<n> {store-macro}   Start recording named macro
X      [end]       Stop recording named macro
```

```
     X{execute-macro-n} Execute macro n (where n is from 1 to 20)
     X-------------------------------------------------------------------------
     X=>       (20) SPECIAL KEYS
     X
     X^G       Cancel current command and return to top level of processing.
     X^U or         Universal repeat.  May be followed by an integer (default = 4)
     XM-<digit>     and repeats the next command that many times.
     XM-X      Execute a named (and possibly unbound) command
     X
     X
SHAR_EOF
if test 8410 -ne "`wc -c < 'emacs.hlp'`"
then
     echo shar: "error transmitting 'emacs.hlp'" '(should have been 8410
characters)'

<Summary: here's one way to fix it, are there better ways?>

I have an early 520 ST with the new ROMS and the 1Meg upgrade.
For the past month (since the ROM upgrade), the system has been
crashing frequently. The crashes have come in the form of lockups,
spontaneous resets and the disk suddenly appearing to have nothing on it.
None of these things were permanently fatal; time, repowering
or jarring the ST would temporarily fix the problem.

Anyway, after much fooling around, I discovered
that the voltage to my ICs was low (about 4.8 volts).
I assume the extra bank of RAMs and extra ROMS (it was shipped with
just the two) caused excessive current drain.
In poking around, I noticed there was a choke in the path of the
5 volts that was not in the developer's kit schematics
(L29 or L39 I think). This choke had a DC resistance of about
1/2 ohm and with my system had a voltage drop of about .4 volts
under load. My current fix to the problem was to place another
choke (of high AC impedence and about 1/2 ohm DC impedence) in
parallel with the first. This reduced the DC drop across the
inductor and raised my IC voltages to 5.0 volts.

The questions- Do all STs have this inductor? What's it for?
Any idea of what it's value is supposed to be (both DC and AC impedance)?
Am I effecting anything else by changing the value of this inductor?
Is my problem really a low voltage coming in from my power supply
(I have the older style power supply), or is it that inductor?

The system has behaved much better since I made the change, but I'd
love to know if there's a better/safer fix!

Thanks!
     Walt Christmas

I have finally, after many attempts, received a uuencoded file thru BITNET
which I could uudecode and run. Who is the lucky person who accomplished such
a monumental action? Simon Poole. Thank you Simon for wonderful foresight
and understanding of the problem with uuencoded programs. The problem? Others
may ask. Yes, the problem I experience (due to some gateway) is two:

1) Tab expansion. None of the proff files I receive ever shell correctly
    due to this problem.
2) IBM machines love to pad lines to 80 columns. What does this mean? This
    means that uuencoded programs having trailing spaces added (which I remove
    when I receive them on the 3B20) do not uudecode correctly. Nor do the
    ones with the spaces left on. Not until Simon hit upon the key.

Solution: add an extra letter at the end of every line in a uuencoded file
           sent over BITNET, to insure that the contents are not altered.

BRAVO!! BRAVO!!! BRAVO!!!!
I can only too heartily recommend that everyone who sends files should adopt
this method.
    Ah yes, and now his program...
I like it very much. It is excellent public domain software, as it is now.
If he were to market it, the program would certainly have a place, seeing that
ansigraf is like it, and does not really have all the same features.

Again, thank you Simon.

Mike V.

Anyone who tries to write a prime factorization program is silly because
primes have only the trivial factors 1 and p where p is the prime in question.

This letter is in reply to Mike Vederman, because I couldn't reply directly. Sorry for any inconvenience.

Mike, you got the button down solution right on the nose. If you add an evnt_timer call to the evnt_button, you can avoid the problem of vq_mouse posting events. Thanks for the help.

The basic arguments seem real sound as presented by this gentlemen and
I myself wondered why it would be so difficult to add memory management.
I wish that he had worked on the ST!!.

||Consider that (for) a simple paging mmu... we are talking under $45 at
||the shelf. This is the difference between the ST being a game machine and
||having the support for process issolation and error detection for a strong
||bussiness machine.
|
|I don't quite buy that. Look at the #1 business machine -- what kind of MMU
|does it have? The Atari has just about the same features as the IBM PC --
|including lack of reasonable system software. The Amiga at least made an
|attempt to make up for the lack of an MMU with good system software.

The IBM PC has a better MMU than the Atari. While segment registers
are awfully annoying if you try to program the 8088 as a machine with
a 20 bit address space, they do provide you with a memory model that
is very similar to the PDP-11 with separate I/D. That is probably
one of the reasons why there is UN*X for the IBM PC but not for the
Atari. You can achieve a similar effect by using only indexed addressing
on a 68000, but on a 68000 you really lose a lot by doing so.

Thomas.

Just recently there was a fair amount of discussion in net.micro.amiga
about the difficulties of making shareable code. One of the biggest
difficulties is generating code which can use distinct parts of memory
for data for each of the processes/tasks/threads/whatever sharing the
one copy of the code. There are ways of doing this for the 68K, but
unfortunately none of the compilers currently available for the Amiga
do this well, if at all. Protection issues aside, it sure would be
nice to be able to compile & link my program so that it uses a data
segment starting at some particular address which gets mapped by
something MMU-like to the address of a memory block allocated by the
OS when I start to run the program.

And hey, I could do that for the code, too, and keep executable images
on the disk as a memory image, instead of a "hunk" file, so that
loading the program consists of allocating memory, reading from
the disk into memory, setting the memory map correctly, and going.
The hunk scheme used by the Amiga results in the CPU having to touch
everything when loading a program, even if you had a hard disk with
fast DMA.

There are real advantages to be had from a simple address mapping
scheme. Protection is nice, especially on a multitasking machine,
but is a separate issue. Demand paging, implying the ability to
restart an instruction which faulted, is yet another separate issue.

This is only a note on John Bass's article about a way to do virtual
memory with little or no extra cost in time. There is a catch to
hiding MMU operations between RAS and CAS, though I do not know whether
this applies to the ST. The high speed CAS only block transfer
operation available in many DRAMs is rendered useless since contiguous
column addresses in a DRAM chip are no longer contiguous in 68K's
address space. I am not familiar with the graphic hardware of the ST,
but the block transfer modes of the DRAM chips are well suited for high
speed sequential access of blocks of memory that is typical to bitmap
graphic systems.

More rumor mill material: this sounds too good to be true (I wonder if Neil could comment):

Compute's Atari ST, October 1986, p. 10, ST News & Notes:

Overheard during dinner at Pacific Fresh, a Sunnyvale seafood eatery just a stone's throw from Atari Headquarters on Borregas Avenue:

Atari's next computer will attempt to penetrate Fortune 500 companies in a big way. To be announced and shown in November at the Winter Computer Dealer Exposition (COMDEX) in Las Vegas, the Atari GST (the actual name varies depending on the day of the week) will be driven by a 32-bit 68020 microprocessor with a whopping four megabytes of memory. A two-meg version of the GST may be shown in the U.S., but will probably be marketed only in Europe.

The GST's operating system will be a System V-compatible Unix, although a hardware switch will allow the system to be booted in ST mode to run ST software. A 20- or 30-megabyte hard disk drive will be standard along with an MS-DOS emulator and built-in networking capabilities.

Even more interesting is the GST's monochrome-only screen display, which will be vertically oriented and boast a resolution of 1024 x 1024 pixels for true workstation quality. It's said to include most of the functionality of AT&T's BLIT (Bell Labs Intelligent Terminal).

At this point, Atari hopes to start shipping the GST by the end of the second quarter in 1987. T-NET networking software is planned to be available in the third quarter.

The price of this package should send severe shock waves throughout the industry: Watch for a sticker price around $1,995 to $2,495, plus a network-capable laser printer for about $1,000.

You always have to specify image mode when using mainframe Kermits.
They default to text mode, which for Unix systems means a single
line feed delimits lines, whereas most other systems use both a
carriage return and a line feed. If you transfer a file using text
mode, the Unix Kermit looks for line feeds and replaces them with
CR/LF sequences. If you want to send a file with absolutely no
translation of the data, you use image mode. (Boy, if you really
want to get screwed up, try Kermitting to an IBM style system that
uses EBCDIC! Then the difference between Text mode and Image mode
becomes *really* obvious...)

This isn't really too much of a problem, since implementing page mode
operations for the processor is really not much fun without some clues
from the cpu (see Fairchild Clipper and Z80,000). The big loss is with
graphics, especially with video DRAM, since you loose the linear relation
between addresses and shift-register or page mode accesses.

Of course one can argue that the display memory need not be relocated,
perhaps just protected via a storage key of some sort, but then your
system is starting to get complicated...

Where are you?

Can anyone out there supply me with the sources to the MAKE.PRG
distributed in the STarter kit? (or better yet, one which has been
fixed...)

I'm trying to use make for modula-2, and the MAKE.PRG I have, doesn't
seem to run .PRG (GEM) files properly. Also, TDI's command line
interface seems screwy in that the compiler doesn't append the current
drive:directory to the command line file name. So, the compiler never
finds the file on the first try and tries to query the user (poor
me...) Since MAKE didn't launch the compiler properly (the .TTP cursor
is still blinking!) I can't interact with the compiler.

Result: REBOOT!

I'l post the fixed MAKE if someone would be kind enough to send me source.

If you are talking about nibble-accessible rams, the ones that I saw
operate only on mod-4 boundaries and each time you strobe the CAS they
return the next bit circularly (mod-4). Since the memory management
schemes that I am familiar with use 2^N boundaries (N > 2), this should
be no problem. But then, you might be talking about another (even newer)
type of ram that I'm not familiar with.

Speaking of which, does anyone know of a REAL (ie - available off the
shelf, now) system that actually uses the nibble mode of some of the
newer rams. It looks like a great way to load your cache quickly with
some of the bus-hog multiprocessors that are becoming available now
(Encore, Sequent, etc...). They already load 64 bits of memory at a time
onto the separate processor cards when they need to hit main memory.

>If you are talking about nibble-accessible rams...

There are many types of RAMs where accessing columns is faster than
accessing rows. Nibble mode, where you can toggle CAS and get out 4
bits; page mode, where you can drop CAS, set up a new column address,
and enable CAS again; and static column mode, where you can just change
the column address on the fly, wait the column access time, then look
at the data. There are also video RAMs which scan data out serially by
columns.

>   ...does anyone know of a REAL (ie - available off the

I do not remember if the new cached Sun uses nibble mode (or other
fast column mode) RAMs.

Part of the problem is that designers don't want to require nibble mode
RAMs, since they usually cost more than "any old RAMs". Designing to
the least common denominator in RAMs [modulo what speed you need]
is very useful for reducing prices.

I've a question for the Atari folks about the MS-DOS emulator. Will this device be interruptable from the ST? It would be very useful for the ST to work with it like a debugger board. For example, I write a program for the MS-DOS environment and wnat to debug it, but my code bombs under MS-DOS and I can't find why. Enter the ST. With a simple double click on the right mouse button, the ST stops the 8088 and saves its state. An MS-DOS debugger takes over on the ST side and displays the line of errant code with the SEGMENT:ADDRESS. This would let the ST run as a Periscope (c)? type product. I've used a few co-processors before, and the most annoying problem with them is the lack of programming control that the host has over the parasite board. I think this debugger suggestion is useful because many of the ST users who would buy the emulator want it for software development. I know I would sure appreciate a feature like this for the times when I need to write an MS-DOS utility but don't want to go into the office and scrounch up a machine. Who in her right mind would want to run PC software when she had an ST?

BTW: I ordered my 1040 ST from a local dealer one month ago. The hard drive came in in a week. But the dealer *swears* ATARI will not return his calls or give him a definite delivery date. To coin a phrase, "I want my ST!"

>
>John Bass (DBA:DMS Design)

Gee John, around here we smile when we say 'Toy Computer...'.

I think you are making a mistake in confusing intent with ability. The
engineers working at the consumer level would love to slip in an MMU function,
but when the time comes to meet to cost criteria, it gets crossed out with a
long sigh. The cuts are on dime and dollar issues, let alone a ten!

The engineers in Shivji's gang, prior to moving to Atari were working on a
Z8000 based game/graphics/unix type box. It had a MMU, which coincidentally
did translation in the RAS/CAS delay. The ST can be viewed as a 68000 based
derivative of this effort.

The Amiga, on the other hand, consists of a high-performance graphics processor
complex, memory and display, with a 68000 added on to tickle the graphics chips
and interface to the real world. In a sense the software exists to drive the
engine, not the engine existing to run some generic software.

The real obstacle to putting in an MMU is the lack of any real world software
at that level that would make it seem a neccessary item. Unix tends to make
the minumum machine too expensive (hard disk and license fees). With two years
of hindsight, OS/9 68K level 2 might look like a good choice, but even now,
Microware doesn't seen too speedy in delivering their Amiga and ST ports.

net.micro:5964 net.dcom:1235

I run a Unix Based multiline BBS system which features a wide variety of discussion groups (over 50) on various computer and non-computer topics. We also feature a download section with good support for Commodore and Macintosh computers (with growing support for the Amiga and Atari ST). The system is up 24 hours a day, 7 days a week on 5 telephone lines. All lines support both 300 and 1200 baud communications.

In addition to the BBS and downloads we currently have a game of "old empire" on line. Anyone may play but the game is limited to 32 players and currently has a short waiting list. For info on empire checkout net.games.empire.

Obviously a system of this size is not cheap to keep running so we do charge a monthly fee of $5 which goes towards paying the phone company (those business lines are expensive!), maintaining the hardware and slowly paying off the purchase price of the computer & modems and other expenses. The monthly fee may go up somewhat in the comming months because of telephone rate hikes, call the BBS for current information.

We have one of our phone lines available for limited free use by nonsubscribers who want to see what our system looks like. The line allows you to look at all our current discussion groups and our download section...but you may not write messages or download programs without a subscription.

The free demo number is (219) 277-5825 300/1200 baud 24 hours

If you want to subscribe please try to call the free demo number and read the introduction to the system first. We normally do not acknowledge the recept of a subscription other than by crediting it to your account (at these prices we can't afford to phone or write everyone). If you need a recept please send a stamped self-addressed envlope.

NOTE

Please don't flame me for a "commercial posting" the system described above just makes enough money to pay the operational expenses, it's not really a commercial venture (it doesn't make a profit or pay me a salary). The system was originally intended to be developed into a national on-line service like Compuserve or Genie but we have not been able to locate anyone interested in investing in the project yet (hint-hint anyone interested?)

The software is for sale <this bit is a little commercial but I include it because everyone always asks> but only as a custom-installed system taylored to a particular applications needs. (it's great for customer support systems)

If you send me net mail please use the address below, don't mail to the address in the article header, or your mail might get lost.

<<<< >>>>

Help!
  My spelling is really pretty poor, and I would like to have an
on-line spelling checker on my side in the war against typos. The
environment I want to use is the vt-52 (or st-52) terminal emulator
desk accessory. I am using my 520ST (1 Meg, TOS in ROM, 2 SS drives,
Monochrome) as a very nice, and intelligent terminal to a Vax 11/780
running 4.3BSD. I use vi on the vax and would like to have something
on the atari that checks my spelling in real time.
  I have looked at Thunder (copyright by someone) and I am not sure

if it is capable of being used with the terminal emulator desk
accessory. I have looked at hippospell and I don't think that it
is a real time spelling checker. I really have to have it real-time
and while using the terminal emulator.
  Please! anyone! with any ideas, or personal experience with
Thunder or the like, let me know.

         Any response is greatly appreciated!
              Thanks,
              Bob

Speaking of the new SUN, I just saw it come through "The Monthly Report" in the August UNIX Review. For folks who may not have seen it, here are (what I consider to be) the highlights.

> "Designed to address those traditional scientific/engineering tasks that tend to be computebound (such as electrical and mechanical CAD, geophysical analysis and AI), the SUN-3/200 series features the 25 MHz 68020, a 20 MHz 68881 floating point co-processor, and a proprietary MMU."
>
> ... talk of 4 MIPS integer performance ...
>
> "Also available is SUN's optional Floating Point Accelerator (FPA) which is said to perform 32 and 64-bit floating point calculations at rates as high as 865 KFLOPS, according to the workstation vendor."
>
> "To maximize throughput, the machine has a 64 KB virtual-address, write-back memory cache and 64-bit processor-memory bus. The 3/200 also comes with up to 32 MB of memory, and -- with teh use of four of SUN's new 575 MB disks -- up to 2.3 GB of mass storage capapcity."
>
> "SUN is showing the new machines at trade shows this month (AAAI and SIGGRAPH), and is promising shipment within 90 days. The price on the SUN-3/260HM (high-resolution monochrome) base system, including 12-slot card cage and 8 MB memory, is pegged at $33,900; with a 280 MB disk drive and 1/4-inch tape, the cost goes up to $51,500. The base configuration for the 3/260C (color) station is $44,900; with disk and tape, $62,500."

Since this may not thrill atari and amiga folks, I restricted followups to this message to net.micro.68k.

> Enjoy...

I, too, run a Public access UN*X system. It has been running over two years now. It consists of an AT&T 3b2/300 with 8 phone lines. We run the PicoSpan conferencing system (The same program The WELL runs) plus full access to UNIX. 4 of the lines are available to any interested person, with access to UNIX, and PicoSpan. Guests do not have access to usenet or off site mail. There are also two contributor only lines. Contributors ($50 a year) have access to off site mail (uucp) and usenet. I also have two dedicated uucp lines. (I feed news to a number of large sites). All modems are 300/1200/2400 baud.

Main guest number is 312 283-0559.

(For what it's worth, possibly but not necessarily equal to what it cost)...
Your fix sounds eminently reasonable to me. The choke might be for RFI and
spike protection. Finding a better choke (same inductance, lower series R)
might be still better, as shunting the existing choke will reduce the
inductance as well as the series resistance. The only penalty then may be
the cost of the choke, which is probably not a problem if viewed as part of
the cost of the upgrade. Shucks, even buying a heftier power supply would be
a cheap way to get a 1MB ST, starting from the current $495 price of the 520!

Subject: Questions on BITBLIT, Malloc (not malloc), and 68 Disassemblers
Message-ID: <514@elmgate.UUCP>
Date: Tue, 2-Sep-86 11:22:08 EDT
Article-I.D.: elmgate.514
Posted: Tue Sep 2 11:22:08 1986
Date-Received: Tue, 2-Sep-86 21:08:24 EDT
Organization: Eastman Kodak Co., Rochester, NY
Lines: 57
Keywords: Line-A disassemblers, memory allocation GEMDOS MPB's

I have some questions I hope someone can reply to:

1. The short discussion in the 'Best of BIX' column in the latest BYTE magazine tantilized(sp?) me into wanting to know more about the LINE-A bit blit opcode ($A007). The structure was given but no mention of the what the fields represent. I could guess at some but that could take months. Could someone get me started by posting a commented view of the BITBLIT structure in the article?
ie.
```
struct BitBlock {
        short    b_wd,b_ht;    /* Width and height of block in 'xunits' */

    pixels/words/bytes

        Get the idea??
        short    plane_ct; /* Video planes ??? */
        etc ..........
```

Any help would be fine. I've worked with the Mindset PC, and the Amiga. so bit-blitting (or blasting as I like to say) is not completely out of my grasp. I just need to know the 'units' for each structure field.

2. What exactly ARE the KNOWN bugs in the ST's memory allocation system? I find sometimes I have missing memory, other times everything is fine. I don't seem to be able to find a pattern. One person says you can have no more than 512 Malloc() calls, the GEMDOS manual says 20, and my own program seems to allow 120. Could someone on the NET give a short run down of what Malloc()'s real behavior is? It seems to me any bugs in something as vital as memory allocation is a real loser, and knowing the bugs could save many a programmer many a late night fiasco.

3. Does anyone know of a an ST disassembler in the PD? Or one that is 'easily' ported? Preferrably one that's output can be redirected to a printer.

4. Related to memory allocation.... Has anyone understood the Memory Parameter Block concept in the ST? Is this related to GEMDOS's free memory list. If so I'd try and write some working allocation routines (assuming Malloc is broken, see question 2) maintaining the system memory list myself, thereby not breaking the loader. I looked a the MBP block in the system's variable area but nothing seemed to be linked to the three

pointers in each. Further, after an allocation, nothing changed. Anyone understand how and where the SYSTEM's idea of free/allocated memory is kept?

The line-a question is the most pressing for me right now. Email if you think it's of limited interest. However the memory and disassembler questions would be of interest to many (I think).

    Thanks,

    I recently purchased a combination ram disks/printer spooler from a company called power systems. The ram disk works fine, but when I set aside the memory for the printer spooler, the time speeds up by a factor of 4. This gets to be a problem, within a half anb hour its already 2 hours off.
    Has anyone else out there had this problem with other printer spoolers? Has anyone used this one?

              Thanks for any ideas,

(Sorry to dissappoint you, but this message is not going to
 decrease the current #Questions/#Answers ratio. It contains
 juicy info for the Language Conoisseurs among you, however.)

Hello,
     does anyone have some information on MicroMumps for the ST?
I know there is a CP/M version of Mumps which could be used via a
CP/M emulator but I rather prefer a real 68000-based Mumps interpreter
for the ST.

{For those interested: Mumps is a real old oddity among computer languages.
 It is interpreted or mixed interpreted/compiled, has a terrible syntax and
 program structure but a beautiful tree-based way of dynamically storing data.
 Examples:
    MYARR(1) is an element of an array in memory,
   ^MYARR(1) is an element of an array on disk, no OPEN/CLOSE etc. needed!
 Subscripts can be strings: ^OBJECTS("HUMANS","John","FATHER")="Bill"
 so you can build a database or knowledge representation system rather fast.
 Other features are powerful string manipulation/pattern matching and, in
 the original language definition, multi-using + multi-tasking.
 Adherents can often be recognized by their religious attitude (cf. APL, Lisp,
 Unix monks), meditating on single-line system exploders. }

hello there,

Does anyone have any ideas, especially with code etc., of previewing
the LaTeX output (the .dvi file) using the ST? I am using the ST as
a dialup terminal to a VAX running 4.2 Un*x. It seemed to me that now
there is a graphics terminal emulator (Tektronix 4014 thanks to Simon
Poole) that there might be a way. This would be *real* useful to me
in my vain efforts to finish a thesis!! My only other option is to go
on campus and use a Sun, which takes a couple of hours.

Any thoughts anyone? Thanks for listening

                  Andrew

Keywords: uudecode emacs ST kermit errors

It's me again. I took the 3 part microemacs posting (uuencoded), glued the parts together (carefully), removed all the headers and signatures, and uudecoded here on a Sun system. Next I took Ckermit and transmitted it to my ST using PC/IC in the kermit image mode and the unix command line :
mysystem% ckermit -i -s emacs.ttp

BOOM BOOM. Bus errors when executed. Ok. I downloaded the uuencoded file to my amiga (using Xmodem) and uudecoded it there. I shoved it over to the ST to execute (also using Xmodem).

BOOM BOOM. Bus error. Ok. Take the uuencoded from my Sun directly to the ST using kermit in the non-image mode (text). Uudecode it.

BOOM BOOM. Bus error. ARRRRRRRRRGHHHHH!!!!

Now I know the files (3 of them) were not tuncated as they all had signatures on them. None of the 3 uudecodes ever complained. Not Unix, or the ST's (compiled under MegaMax), or the Amiga's (compiled under Manx).

Is there a point to this? Sure is. Just for the thrill of it I decided to uudecode the cadenza.prg and the levy.ttp that were posted eons ago. Cadenza came up with TOS error #35 (too many files open?????). And levy just started and exited.

So I have yet to uudecode any posting for the ST, on three different machines, and have a working program. Up till now I guess I did not care. But me3.7 (and the recent GEMKermit) are exceptions. I want a decent editor that supports long (>80 chars) lines. And Gemkermit would be nice. Gemkermit has all it resources uuencoded.

Has anyone else successful uudecode anything and had it run on the ST? What might I be screwing up? The few binaries posted for the Amiga uudecoded fine on the Amiga and ran. The unix binaries I've decoded also run fine. So you'd figure I could get an ST binary to run? No way!

Could someone help on this? Could the diffs for me3.7 under MegaMax be posted or mailed to me? Thank you for your support (B & J).

I have had the same symptoms after upgrading my 520 to 1Meg and,
hearing (reading) the chatter about problems and weaknesses with the
original power supply, was ready to swap it for a new switiching power
supply or something. Recently, though, I talked to a hardware hacker
type in the East Bay (east San Francisco Bay, that is) who told me
that the original power supply, bad though it is, is not where the
problem lies. He has done (and repaired) many ST upgrades and his
procedure includes changing an inductor on the right side of the ST
board (with the RAM at the bottom or toward you). The original coil
is rated at about 4.something micro-henries. He replaces that with
one of 2.2 micro-henries or less. His claim is that this will prevent
the power drop to the RAM that is causing the problems. He also adds
an additional buffer chip. I am unwilling to post what I remember
of his instructions since I am not a hardware engineer or very knowlegeable
of such things and I would mislike being the proximate cause of someone
frying their ST. If there is any interest from the net in complete
instructions, I will try to get him to write them up and I will post
them. I would also be interested in comments from other hardware
people about this approach.

["Nice jail. Looks strong." -- H. Houdini]

Well, I found a system bomber and I don't remember if anyone else has
mentioned it. If you have TOS in ROMs and you are at an Item Selector
box and you want to change the directory path to go into a folder that
has an underscore ('_') in it's name, forget it! The instant that you
type the underscore, it will bomb out! I have tried it om several
different STs an they all do the same thing! What I suggest is to stay
away from using the underscore until Atari comes out with a new TOS ROM
set. (Hey Atari, any plans for that?).

I also was unable to do anything. I didn't get the TOS error 35, but when I ran a crash utility, I saw that I had a bus error.
I catted all files together after removing the signitures. Then I uudecoded it without error, then I used xmodem to transfer it to my ST and VOLIA, it didn't work.

I might be able to specify a fix (via SID) if the aforementioned printer is NEARLY Epson FX-80 compatible. I used to work for Migraph, Inc., and wrote a fix program for the Gemini 10X (available on CompuServe and local BBS). That was a matter of adjusting the vertical spacing (from 1/216 to something else, I think). FX80.SYS is rather hardware-specific, though, and won't allow much tampering. Migraph will be coming out with drivers for laser and color printers in the future; others, I can't say.

Now that I have alot of DEGAS and NEO pictures,what I need is a way to
reverse them so that I can get a heat Transfer ribbon for my printer and
print them on T-Shirts (my kids will love that). is there a program that
will reverse pictures????What about taking out the colors??

Bill

Also wanted more pictures(I like using them with the slide shows)

     This really emphasizes the importance of posting real source code instead of Uuencoded files. Often a slightly broken source can be repaired without reposting the whole code. Uuecoded files are generally scrap when they are busted. It makes me wonder how much Net time is going to be wasted because of the bad MicroEMACS sending. If it's re-sent, how much confusion is going to result?

Cheers! -- Jim O.

Trying to overcome the problem with LINK68 not accepting pathnames I found
a scanner control table starting at file-offset 0x8144.
The command scanner of LINK68 uses a byte entry of this table indexed by an
input character as a control pattern specifying the character class.

The backslash entry at file-offset 0x81A0 has the value 0x02 which is a
separator pattern.
Patching it to value 0x04 puts the backslash into the number class.
After this fix LINK68 treats the backslash as a normal identifier character
but GEMDOS still sees a pathname.

Does anyone out there have, know of, or know how to create a replacement
for the FX80.sys file that will drive a C-Itoh Prowriter 8510? I hate
to think of trashing a very good printer to use one piece of software.
Rick Newton
University of Massachusetts - Amherst
/* ---------- */

I'd like to have a driver for the C.Itoh 8510 as well. I know that Atari-Benelux
has released such a driver for their SMM800-printer (or whatever they call that
thing). But there are no directions included for adapting the driver to any
other printer. And I just don't feel like comparing the FX80.SYS against the
SMM800.SYS or even disassembling the two.

I hope that someone comes up with a solution, Michael.

Eastman Kodak Company
<Kodak won't be responsible for the above comments, only those below>
/* ---------- */

Some time ago the West German computer magazine "Happy Computer" released
a special 68000-issue. There was a PD-Disk available, that featured most
of the Atari-ST-programs as executables and some of them even as source.

Among these programs was a PD-ML-monitor (somewhat bigger than 8KByte)
with some excellent features:
- display/edit memory in hex/ascii
- load/save files from/to disk (Sorry, no loading for execution like SID)
- tiny disk monitor
- disassembler
- single stepping/tracing of instructions
- output redirection to parallel or serial port
- advanced find capabilities (hex bytes, strings, wildcards, 68000 instructions)
  [to find all MOVE.Ws yoy say: f "move.w" start-address end-address]

I'm willing to post the executable, if there's enough interest on the net. But
there's one problem with the documentation: it's in German. Although this is
my mother tongue, it may be not your's. I might be convinced to attempt a
translation, if I get tremendous feedback. But that might take a while to get
accomplished. I'll even consider sending the assembler sources (BIG: ~>50Kbyte),
if the responses are overwhelming.

In article <517@elmgate.UUCP> jdg@elmgate.UUCP (Jeff Gortatowsky) writes:

>Has anyone else successful uudecode anything and had it run on the ST? What
>might I be screwing up?   The few binaries posted for the Amiga uudecoded
>fine on the Amiga and ran. The unix binaries I've decoded also run fine.
>So you'd figure I could get an ST binary to run? No way!

I just finished putting together uniterm.prg, uudecoding it on an 11/70
running UNIX v7, and transferring it to my ST using Xmodem. Simon
Poole was decent enough to indicate how many bytes to expect in the
uudecoded version, consequently I was able to check that the uudecoded
version was the correct size. When I looked at the Xmodem transferred
version on the ST it was 16 bytes larger. I obtained a hex dump of the
beginning and end of the uudecoded version and compared it to the
version on my ST and found that there were extra characters at the
end of the program. After editing these out using H&D's Tool Box,
uniterm.prg worked fine.

My success with program transfers has been varied. This is the first time
I was able to recover from what I thought was a failed transmission.
The next time it happens I will certainly check the byte totals on both
machines. It was nice to have the actual byte total to check whether
the posting arrived on our 11/70 successfully. I hope future postings
include this feature.

I have had a similar problem with uudecode/encode recently. As it turned out
I uudecoded a file on a Vax, and on the ST. But voila the file lengths were
different! This got me curious since I trust the UNIX version more than the
ST version I did some checking. As it turned out the ST version of uudecode
opened the file it was writing in ascii mode, this posed some problems with
traslation of the new-line chars. Anyway hacking the code for uudecode to
use fopenb instead of fopen and recompiling it fixed the problem!

I teach a writing course at this university and have been developing a
set of programs too run on an IBM-PC and a Vax system. But my
computer is an ST. I would like to be a little subversive and demo
the "environment" on my 1040 (color). Our school has large screen
projection TVs that they use for demos with Apple computers. Since
the demo will be for our entire department, I would like to be able to
use the projection system (Sony).

My question is what do I need to connect the ST to a system like this.
Or what more info would one of you kindly readers need to help me out.
There is a DIN and an RCA (phono plug) input on the projector, but the
department that maintains them doesn't know much about the technical
info, and the technical info guys don't know anything about computers.
So I'm pretty much on my own. Any help would be appreciated. Who
knows I might be able to convince the department that it's time to
develope an ST based writing lab!

Subject: Kermit for ST?

I need to get a version of Kermit for my newly-purchased 1040ST, and am
wondering which is the correct version to get. Could someone please tell
me? Please respond directly, as my name doesn't seem to have made its way
onto the list yet.

Thanks.

What is the availability of one-meg upgrades for the 520ST other than
the "piggyback-ram" methods posted on the net. Are there any plug-in
(plug-over, hang-on-the-side, whatever) boards available? Does anyone
have any experience with any of them? Cost? Caviats?

> Has anyone else successful uudecode anything and had it run on the ST? What might I be screwing up? The few binaries posted for the Amiga uudecoded fine on the Amiga and ran. The unix binaries I've decoded also run fine. So you'd figure I could get an ST binary to run? No way!

I have had exactly the same experience. I couldn't get the uudecoded Cadenza files to work (TOS Error #35 just like you got), but I didn't care much since I had no trouble recompiling the sources and getting a working version that way. I brought GEM Kermit over from Columbia but couldn't get the resource files decoded properly so that they could be read into the resource construction set that came with the developers kit. I haven't even tried to use the new uEMACS.

I too would appreciate any advice on what might be going wrong.

Lines: 22
Summary: Don't use BRA.S -n(PC)

[]

Seems that the assembler built into the Megamax C compiler has a bug:
BRA.S n(PC) with a negative n yields pretty much random code. The same
holds for Bcc.S.

Note the absolute displacement. I am not sure if it works right with labels.
Changing it to a word displacement (BRA instead of BRA.S) fixes it.

Usually you would use labels, and also use just plain BRA. The mmimp
program can then be used to convert branches to short ones where possible.
But the fun starts when you mmdis-assemble some existing .o file for
which you don't have the source...

There is also a bug in the disassembler: very large numbers (32-bit)
are sometimes displayed as garbage characters, e.g.

     AND.L #)(&.)/(*.)(,D0

(Conclusion: don't buy a compiler until it's perfect - and obsolete :-)

Yeah!

I have never managed to get ANYTHING uudecoded and running on the ST.
But I have downloaded a lot of source code (including microEMACS and Proff)
using ASCII (no error checking) and had very few problems. (The rare missing
bytes usually were a tab on the left, i.e. it compiled anyway!)

No,no,no,... I meant I'd just like to see the same structure definition that was published in the 68K issue of BYTE, only with the fields of the structure commented as to what units they represent (BYTES,PIXELS,X/Y pairs, words, etc). That is assuming of course it is the correct structure definition in the first place. For example the structure starts with:

```
struct blahblah {
     short    b_wd,b_ht;
     .....
     ....
     lots more stuff...
```

Now I looked at that and said AH HAH!
     block width and block height.
Hmmm ....in pixels? Must be. Well maybe not. Hmmm.

The offsets (word,line,plane) really are the ones I can't deduce from looking at the structure. Offset by what? Word offset? 16 bits right? Or 1 for one word. Plane offset? I thought the plane offsets were 0,1,2,3 words depending on color choice (or something like that). I'll muddle along figuring the rest out. Just get me started with a commented structure definition. Please?

As for the Line A doc you mentioned, my developer buddy told me on the phone that it says 'see the end of this document for a description of BITBLT'. Only there is no description to be found! I asked him if the 300

bucks was well spent? He hung up.....

8^)

   Does anybody have specs on the Atari SMM804 printer. I need info
like speed, compatability with other micro's, what ribbons does it
use...etc...

   Also can anyone help me on this one:

    I just bought the Developer's Kit(sic) and I was using some VDI
calls and I noticed that when I changed the color using vs_color of color
3 (which is green by default I think) to blue the desktop also turns blue
Is there anyway around this besides making another call to vs_color with
the original rgb numbers.

Thanks

C: GST C is suppose to be good/cheap, although it doesn't have floating
    point and some other features; I haven't used it.
    Mark Williams appears to be good, and it's cheap around San Jose (:-)
    but I'm waiting until I can afford a hard disk before I buy it (:-(
    Beyond that there's Lattice, MegaMax, and the developers kit in
    aproximate increasing order of cost, though not necessarily quality.
    HIPPO C, (even if you can still find it) is not worth the money.

Modula-2: The only choice appears to be TDI Modula-2. I have a friend who
           has it, and says it is a reasonable implementation but the
        manual is limited.

Pascal: OSS Personal Pascal is the best choice here. I have it, and
         have written GEM applications and a desk accessory with it,
      and am in the middle of both MIDI software and a CHESS program.

     If you already know Pascal, or don't know any of the above
languages, I would recommend Personal Pascal highly. Especially if you
don't have a lot of experience with GEM on the ST yet. It's a fairly
full implementation of the ISO standard with a few useful extentions,
it has seperate compilation (mediocre) and a good library interface to
GEM along with reasonable documentation in the manual.

     So far I've only found one nasty bug, and its fairly easy to work
around.

     I would not recommend Pascal if you are already a C hacker and
don't know Pascal though. In this case, you'll find the language very
restrictive.

help! imagine my frustration, all that work and no one can run it, i
don't want to start the sources vs. binaries debate again (i am on
the sources side) but i think i stated my reasons for not posting
the sources and being an obstinate &^%&$ i will stand by them.
meanwhile back at the ranch, does anyone have a better way to
distribute binaries then uuencode ??????

someone recently posted comments about some mailer deleting trailing
spaces and therefore screwing up uudecode postings, i am going to
use their method (adding a char to the end of each line) and mail
them to some of the people who couldn't use the last posting. if
that works we'll go from there, sorry

I have successfully uudecoded ue 3.7 and kermitted it to my ST.
It appears to work on my mono screen, though it appears to be
set up for 43 lines (EGA PC screen) so you need the little HI50
program to get it to work. I used image mode on both ends of
kermit. I used the kermit that came with the developers kit

when I bought it about a year ago. I got problems when I forgot
to use image mode on the ST side. Previous postings, such as the
xmdm program also worked for me. I haven't tried cadenza yet.
Maybe the problem lies with GEM Kermit, but this is only speculation.

    Has anyone heard something about a Smalltalk-80 implementation for the 520ST+ ?

I guess 1MB RAM, a 20MB Winchester drive, a mouse, a bitmapped screen and last not least a 68000 CPU would be a perfect environment for a Smalltalk system.

If there are any rumours, please let me hear.

Thanks,

Does anybody have an intelligent backup utility for the ATARI-Winchester, which can save and reinstall directory trees not fitting on a single floppy.

I guess some other people on the net would also be glad getting a nice backup program.

So if someone has got such a utility, I would appreciate him posting it.

Thanks in advance,

I may have found a solution to the problems of transferring uuencoded/ uudecoded files to STs. I had the same problems as others have described (i.e. transfer the file, run it and get a TOS Error #35) with the recent Uniterm posting. I tried both Xmodem and kermit and got the same result each time. So I loaded the uuencoded file into EMACS, and went to the end. There was an extra line feed and the word 'end' and a couple of more line feeds. I deleted everything except the last line feed on the last line of the file. This, of course, produced an error message of 'Short File' when I uudecoded the file. But I still had 'uniterm.prg' at about the size it should have been (I didn't check

specifically). I went ahead and transferred the file to my ST and
double clicked on it. It worked. Perfectly. I like it. Anyway,
try that on some of the files that have been creating problems and see
if it works. Luck.

If the projection system has an RGB input, all you should need is a cable or
adaptor to make the connections from the Atari RGB output to the right input
connections on the projector. At worst you might have to wire up such an
adaptor.

Summary: Any adaptors available?

[]

I sort of remember seeing something but can't find it:

Does anybody know of some plug available for the ST cartridge port?
I am thinking of something like a board with the right fingers on an edge,
expanded to a more standard width on the other edge, or even with an edge
connector on the other edge. I DON'T need any traces for PROMS.

uuencode/decode is not a hard thing to write, though. I am working on a
version for the Atari 800xl and it looks as though it won't be difficult.

If anybody wants the definition of uuencode/decode coding, I just happen to
have a "functional spec" and also very compatible "c" source code from a kind
soul on the net.

   Does anybody have specs on the Atari SMM804 printer. I need info
like speed, compatability with other micro's, what ribbons does it
use...etc...

   Also can anyone help me on this one:

    I just bought the Developer's Kit(sic) and I was using some VDI
calls and I noticed that when I changed the color using vs_color of color
3 (which is green by default I think) to blue the desktop also turns blue
Is there anyway around this besides making another call to vs_color with
the original rgb numbers.

Thanks

/* ---------- */

Some time ago the West German computer magazine "Happy Computer" released
a special 68000-issue. There was a PD-Disk available, that featured most
of the Atari-ST-programs as executables and some of them even as source.

Among these programs was a PD-ML-monitor (somewhat bigger than 8KByte)
with some excellent features:
- display/edit memory in hex/ascii
- load/save files from/to disk (Sorry, no loading for execution like SID)
- tiny disk monitor
- disassembler
- single stepping/tracing of instructions
- output redirection to parallel or serial port
- advanced find capabilities (hex bytes, strings, wildcards, 68000 instructions)
  [to find all MOVE.Ws yoy say: f "move.w" start-address end-address]

I'm willing to post the executable, if there's enough interest on the net. But
there's one problem with the documentation: it's in German. Although this is
my mother tongue, it may be not your's. I might be convinced to attempt a
translation, if I get tremendous feedback. But that might take a while to get
accomplished. I'll even consider sending the assembler sources (BIG: ~>50Kbyte),
if the responses are overwhelming.

This is fixed in system software version 1.2. AmigaDOS will not put up
a requester asking for a disk until ALL disk activity is finished.

     Regards,
          Paul Higginbottom.

Keywords: ST compilers review
Summary: mark williams C preliminary review

A couple of days ago I purchased MARK WILLIAMS C for about $170.
The package included two Double Sided disks, and a large manual
(the manual seems very thorough). After about one hour I was able
to install a workable version on my system, a 1040st and a single
sided drive. The manual states that MW C requires two double sided
drive (or a hard disk) but I got around this with a
ram disk and some patience (there are single sided versions available
from MW company).

The compiler and linker appear to be fairly quick (quicker than lattice,
or GST...) with the hello world program compiling and linking in about
90 seconds from floppy disk. In addition the libraries seem extensive,
including floating point.

MW C comes with MicroEmacs and a micro shell. IO redirection works,
including pipes (special)! I haven't yet had time to play the editor...

If anyone has test suites they would like me to try please send them
via e-mail...

I will post results... and perhaps have more comments after the manual
is sufficeintly broken in...

MM

Well, I did the upgrade on my ST at work & tho it complains not it doesn't seem to be there. Ok, the questions:

1) Does the freeram.acc I pulled off of the net awhile back actually know if I have > 512k?

2) How do I use the memtest.prg I pulled off of the net? It says it's running a 1M check, but gives no errors unless forced by the mouse. Shouldn't it beef a little if there's a problem WITHOUT moving the mouse? (This question could be a little premature as I only let it run 3 or 4 minutes)

Help! I'd like to get this one flying before digging into mine. It's kind of nice to have someone else's machine to practice on, but it should work.

Thanks, -Leo

BTW, I've managed to uudecode lots of stuff from the net w/out mishap. Are you sure you're setting file type binary when transferring executables with kermit?

I got parts 3-5, the encoded uniterm.prg, and it looks great, but I desparately need parts 1 & 2, which I assume contain the documentation. My main concern is that I need the 4014 emulation, and can't figure out how to get it to work -- while playing around with it I got a couple of random lines on the screen, so I assume that it does work, but clearly i am not getting into graphics mode properly. So if anyone knows how to make the 4014 emulation work but can't send the two missing parts, that would help too.

In the discussion about uuencoded binaries vs. source, everyone seems to
assume that we all have compatible compilers. We don't. For example, I
have the Modula-2 developers' kit, which is very nice but doesn't do
much of a job on C sources.

I've had no problem with uuencoded files though -- I decode them on the
Unix machine that is on the net and send the binaries down using xmodem
or kermit. All the uudecodes that I have seen really seem written to
run under Unix anyway, and maybe this is why they don't run OK on the ST.

Sources for uudecode and xmodem have been posted to the net, and there
are tons of PD xmodem packages for the ST (my favourite is xmdm.tos from
the group at Case, via bammi, which is much more robust and reliable
than the others I have tried). The time may be ripe for reposting of
these sources, preferably with enough defines so that they will compile
on any Unix engine (my versions are heavily hacked for specialized use
on my machine and may not be very portable).

help| I am having some problem with the buffers used for the create
and delete sprite, the call works, but I am damned if I can find out
where the pattarn/save areas of memory are. My documentation indicates that
these are pointed to by a couple of the registers on calling the routine, but
these dont appear to work in the way indicated in my book "Internals of the
ST". Currently I am still running the disc based os, having not yet received
my roms, - is this the problem ?
    thanks in anticipation

Since there seems to be a lot of interest in it, here is the quote I was
referring about Microsoft Word on the ST. It's from InformationWEEK,
7/14/86, page 41, in their INDUSTRY BRIEFS section.

Microsoft Modifies Microsoft Word for Atari's PCs
     Users of Atari Corp.'s 520ST and 1040ST personal computers now have
a word processing program written just for them. Microsoft, of Bellevue,
Wash., has modified its Macintosh-version of the Microsoft Word program
for the Atari PCs. The new version is called Microsoft Write. In addition,
the agreement between the two firms gives Atari, which is based in
Sunnyvale, Calif., worldwide distribution rights to the program.

The other reference to this was in Computerworld, 7/14 issue. It was buried at the end of an article on Microsoft Windows on the IBM PC, and gave the same information.

I have a hardware question about Atari 1040ST's: Does there exist an Ethernet interface for this machine? And if so, what software is available?

My interest is this: I am contemplating getting a small computer for use "at the office". This means I'll mostly be using the machine as a smart terminal (with some local editing). Normally I'd just connect the RS232 port to one of the VAXen (or a terminal server) I use at work, but the serial ports on the VAXen are being phased out in favor of Ethernet-based terminal servers (fewer wires need be strung and less dependencies on particular VAXen). We have two DECserver-100's in the office where I work, but all of their ports are in use. There are several available Ethernet drops available (via a DELNE). If it were posible to put the Atari on the Ethernet directly, I would get much faster file transfer (10Megbit!), than with the DECserver-100's, as well as access to ANY of the machines on the Ethernet (only limited by whatever protocol(s) the software for the Ethernet interface handles). We run several different Ethernet protocols: DECNet between VAXen running VMS & Ultrix, ChaosNet between the LISP Machines (and some of the VAXen running VMS), TCP between UNIX machines (SUN's, HP's, VAXen running Ultrix and some of the VAXen running VMS), DEC's LAT protocol (between the terminal servers and the VMS and Ultrix VAXen).

Here is a little example from this months issue of STuser magazine that
i hope will help. The parameters are set up for a monochrome monitor, but
it should be trivial to convert to color (see comments). You will also
need asmstart.s that i am also including. Assemble both using the
developers system, and link as follows:
     link68 sprite.68k=asmstart,sprite
     relmod sprite

#!/bin/sh
This is a shell archive, meaning:
1. Remove everything above the #!/bin/sh line.
2. Save the resulting text in a file.
3. Execute the file with /bin/sh (not csh) to create the files:
asmstart.s
sprite.s
This archive created: Sat Aug 16 23:59:52 1986
By: Jwahar R. Bammi ()
export PATH; PATH=/bin:$PATH
echo shar: extracting "'asmstart.s'" '(1959 characters)'
if test -f 'asmstart.s'

```
then
     echo shar: over-writing existing file "'asmstart.s'"
fi
sed 's/^X//' << \SHAR_EOF > 'asmstart.s'

Reply-To: bammi@cwruecmp.UUCP (Jwahar R. Bammi)
Distribution: world
Organization: CWRU Dept. Comp. Eng., Cleveland OH
Lines: 23
Keywords: MEGAMAX C PREPROCESSOR

I came across the following bug in Megamax C's pre-processor. It does not
substitute arguments enclosed in single quotes ('x'). My understanding
is that the pre-processor should not substitute arguements in strings
(ie within double quotes (")).

For Example:

```
#include <stdio.h>
#define BROKEN(x)  putc('x', stdout); putc('\n', stdout)

main()
{
     BROKEN(A);
}
```

will always print the character x no matter what the argument to BROKEN is.
Alcyon (v 4.14) and Vax (bsd 4.3) print out the character A as i expect.

>   --jp

This is a possibility, but I think that there are more efficient ways to
rubberband an OR line. One strategy that could be used is to do "reverse
Bresenham": instead of *drawing* a line according to a Bresenham DDA algorithm,
go out to the screen and *copy* the data that is in the area to be drawn
over into some buffer, using the same positioning logic (DDA) that is used in
Bresenham line drawing. Then draw the line. When you move the line, just
replace the stuff you copied from the screen and recycle the procedure.
A bit more complex than the XOR technique of drawing the line twice, but
it does the trick with a minimum of copying and buffer space (which was
certainly at a premium in the 128K Mac).

I have seen this technique used in some Multibus graphics buffer boards.
It's not too difficult and would require considerably less data moving
and buffer space than copying the entire screen. Since Atkinson did lots
of custom code for MacPaint, it is not inconceivable that he used this
technique. But we'll never *really* know, will we?

Keywords: pascal bios xbios gemdos
Summary: has anyone typed in all the procs/funcs?

Has anyone typed in a complete set of definitions for xbios, bios, and gemdos calls for OSS Pascal? I've started it myself, and got halfway thru gemdos when I thought I'd ask here. It's a pain in the neck to type in every definition, and if someone else has already done it, I'm sure that many users would appreciate a posting.

i.e.,
```
procedure Cconout( param: integer or whatever );
   gemdos( whatever );
etc.
```

Its all DRI's fault. First they wrote a memory allocation mechanism for the Atari's OS, which is the most weird mechanism i have seen sofar. It works something like this:

> When an application has done it's startup Mshrink the OS calculates the amount of memory that's left. This amount is divided by 256 and an array of pointers to that number of 256 byte memory blocks is initialized. Every time you do a Malloc (not a C malloc) you will get a pointer to one of those 256 byte blocks. There's yet another setback in this story: the maximum number of pointers is limited to about 512.
>
> So, when i ported MicroEmacs 3.7 to my ST i used Malloc instead of malloc (i thought it might be more efficient: i used Lattice C). You can imagine what happened: Emacs wouldn't read files more than about 320 lines. THE OS WAS OUT OF POINTERS, NOT OUT OF MEMORY.

So every C compiler has to have its own 'linked list' memory allocation mechanism, and so has DRI-C. To find the amount of memory left in the system use Malloc(-1L) instead of malloc(-1L). malloc(-1L) should be a request for 16Mbytes of memory !!. And if i remember right malloc of DRI WILL ONLY ACCEPT SHORT ARGUMENTS (<= 32KBYTE REQUEST)

Hope Atari will get decent OS writers one day.....

Personally, I take great pleasure in writing to the company
whose product I did not purchase due to unacceptable copy
protection methods (which includes most if not all that I have
encountered) and informing them of the lost sale, the reason
why, and usually the product that I purchased in lieu of their
own. I also point out that I have recommended to all my
acquaintances that they also search for another product. One
should also write to the company of purchase and complement them
on their approach and pass on the same information. Indeed, one
cannot teach a lesson without communication. If one cannot find
a commercial or PD product to accomplish what one wants, there
is the option of writing the code oneself. While this is
usually more expensive (person-hours to write the code), it
often is more to your needs anyway.

Don Keen, AT&T Consumer Products

AT&T barely knows I exist and certainly would not wish or be

I understand your first paragraph completely. But you lost me on the second. I can see where a MMU that provides protection only would be useful but address mapping is still of no use. Not without a 68010, admittedly an easy upgrade, but not provided. If you mapped a some address block to another would you not HAVE to ensure it was a legal RAM/ROM address? One faulty address and your back to GURU type crashes, yes? I guess it be nice to learn from you what type of paging you could implement with just an adder, etc. Enlighten me. Mail if you must. Post if it seems of general interest to all 68000 based machines.

>   --jp

Almost. You'll notice that there's no flicker when you move the line,
as there would be if MP constantly copied the old screen buffer onto
the real screen and then did the draw (even Atkinson&Quickdraw can't
beat a vertical retrace on circles that huge). Rather, MP copies the
effected portion of the old screen buffer onto a temporary buffer
(affected portion=union of rectangle within which last instance was
drawn and this instance), does the draw in the temp buffer, and then

copies the temp buffer onto the actual screen.

Atkinson gave a mini-speech here about {software,human}-engineering
about a year ago, and said that using the mini-buffer slowed things
down by about a third, but that it actually looked faster to the user
since things didn't flicker when foo moved them.

Incidentally, this is the way a lot of arcade games used to work on the
old {1,2,4}meg 8-bit machines with fixed screen space, like the Model
I/III TRS-80. Anybody remember Big Five Software?
new screen.

Has anyone had any experience with the Easy-RAM 520 upgrade for the 520ST?
It updates the 520 to 1 Meg and costs approx. $160 here in northern NJ.

Apparently it installs without any piggybacking of the RAM chips.
I've had reports that it is easy to install but have never heard anything
as to its reliability and/or performance.

A reasonable attitute, but remember that both the Amiga and Atari were
intended to be affordable machines. To this end, they contain only those

things that were considered to be needed - no 'it sure would be nice...'
type goodies.

Hi,

You know, I work for this Atari Dealer. And we seem to have some sort of problem in getting ANY Atari hardware in. Seems that Atari either has run out of stock, or do not have enough people in charge of orders for dealers. It is pretty sad, cause we cannot sell what we do not have in stock. On a daily basis we lose sales to mail order, cause people cannot afford to wait for Atari. We have been waiting for "any day now" for about 2 months now. Sigh. It is pretty sad. I dunno, maybe Neil over at Atari can say something. One of the tricks to selling computers at a dealership when competing against mail order is to be able to have the hardware in stock. People cannot deal with "any day now". So they leave, and go mail order. Atari is trying to compete with other major computer companies. But we cannot sell what is not available. "We carry all these, plus the ST which is more powerfull than any IBM machine, but we dunno when we will get one. We DO have the IBM-Compatibles in stock, though" When people go computer shopping they like to get what they buy NOW, and not wait for some non-announced date. If this is the way that Atari Corp. is planning to deal with dealers, it is pretty sad. Selling machines ONLY mail order and in stores like Lechemer's is not very good if you want to establish yourself in the market. Corporations, Schools, Universities (we have 6 around us) will ONLY purchase from a dealer and not from mail order. Business men like to SEE what they are getting and try it out, and get a store to back them up with some sort of service contract. By going only with mail order and such, Atari Corp. is putting itself in danger. In the end one can see a price war like happened before. And nobody wins. Machines are sold below cost, and losses are reported everywhere.

I honestly hope that Atari Corp. sees beyond this mass-volume-sales into the future and establishing themselves as a real, mature, secure and stable computer company which can computer with big blue and others. But by not supporting its dealers, they place themselves in jeopardy. Since, without dealers, they will not be accepted into the business, educational markets in any amount that causes a difference. I like Atari, and I own an ST. I have followed the Tramiels for years. Having started off with a PET 2001, then a C64 and now an ST. I wish to continue being with them, but that can only be done, if they keep up with times. I personally require as time goes on more mature machines with better company support. I believe Atari is more than capable to support ths mature level of modern computer business, but it is something that might take time.

Our dealership is based on Atari business, it being our main line. This might have been a mistake, due to the lack of hardware to sell. But, we took the risk, cause we believed in Atari and Tramiel. We think it can be done. But every month that goes by that we cannot sell a machine cause Atari doesn't send us any, is another month that pushes us closer to re-consider our dream. We are right now receiving strong pressure from our investors to carry another line of computers as our main line,

one which we can have over_stock. Not "any time soon". We are honestly
trying to hold out for Atari, the market in our area is perfect for it.
(College Students left and right, about 100,000 of them, and we are
 the only Atari Dealer). But we need hardware, not promises. They do not
pay bills. I hope that something does work out.

I just bought a 520st mono system and Avatex modem. I have no problems with
it except the one mentioned above. If your not dialing long distance you
can use pulse mode insted of tone mode and hear the number dialing.

Summary: Bad news ?

[Eat this !!]

I had great problems developing applications for use with the
cartridge port. Everything seemed to give me bombs right away.
I finally got a directory up when I built a cart with just names
and "rts"s. I called R Frick's number at atari. I got passed
around for a while but eventually got to someone that appeared to
know what was happening (unfortunately, I forget his name).

He said that application-type cartridges have never worked under any
rev of TOS!!! This kinda shook me up and I questioned him further but
he wouldn't change his story. There is some way around the problem,
that involved booting without disks attached or something but I wasn't
able to figure it out.

Has *anyone* been able to get an application cartridge running ?

>
> --
> Gijs Mos
You can auto-allocate stack space if you always allocate it the same way
so you know how to recover when you get a fault. For example, always
update the stack/frame pointers and then clear a memory location before
actually using it. A bit wasteful, but it may be worth the effort.

I though I heard of someone using pairs of 68000's before the 68010s
came out. One was set to run just a bit ahead of the other, so that
the first faulted, and the second was in the state the first one should
be in when it was restarted.

It may not be cheap, but don't say it can't be done.

We are thinking about students education on one or more
groups of Ataris which are connected by a network. To find
out whether this is usefull we need answer for questions
like:

How many machines can be connected? How is the performance
of the network? Does fileserving, printserving, plotserving
exist? Are there gateways to other networks? Where are the
limits of such networks? Who is producing such networks?

Does anybody have any experience with a network for ATARI-STs?
If so, could you please send me mail explaining your experiences
or answering some of the questions.

Consider that a simple paging mmu is a pal and two highspeed 16k static rams,
a production cost of under $10 in ST quantities, furthermore parity is under
$5 -- at a 3:1 retail price to parts cost ratio we are talking under $45 at
the shelf. This is the difference between the ST being a game machine and
having the support for process issolation and error detection for a strong
bussiness machine. The additional market share should justify it, except for
the mindset of being in the highly competitve game market. If both of these
we included in the custom vlsi, the cost would have been cheaper.

Sorry ... but Atari just screwed up ... this machine is not just another
400/800 in the market place -- it is big enough to go places, but remains
cripled by it's designers.

Subj.: TDI-Modula II/Key Caps/VT100 Emulator

I. TDI Modula II

Yesterday afternoon we received 12 1040 ST's at our institute, which are intended to be used as terminals (and to provide some local processing power). As a programming language we decided to try out the new version of TDI's Modula II. I spent last evening playing around with it and since I can compare it with the old release, its probably a good idea to do a short review.

To start with the positive things: the handbook is better, in an appendix there is a short explantion of Transfer and IOTransfer (but no working examples) and it seems to go a bit more in to the details of the implementation. There are some things missing like good configurations for work with the ramdisk.
There are a BIOS and XBIOS interface included in the libary now and if you buy the toolkit you get some higher level GEM routines plus the MegaMax resource construction program, a GEM version of the ETH debugger and the Versions of the ETH sym and lnk file decoder.

So after a look in the handbook and the moving of all the files to a double sided diskette, I decided to compile the sample definition and implementation modules on the disk. I started the ramdisk that comes with the package and copied all files except the ramdisk and the options accessory to it. I made the ramdisk 700 kB large, that did leave some free space on the disk. To set the search paths for the compiler, editor, linker and debugger (if you have the toolkit) you use the options desk accessory, it allows you to set 4 directorys to be searched for files in the order you specify:

```
Example: 1 D:
         2 D:GEMLIB
         3 D:STDLIB
         4 A:
```

Additionlly you can set compiler and linker options, like dump,debug,optimize, but there is no way to save these settings to disk. The desk accessory does look at a file to determine the default pathes when it is booted, but you have to create this file with a separate editor. So after setting these options I started the Modula desktop program. It looked quite nice, with icons to start the compiler etc. but where were my sample files? Acording to the handbook they should have been listed with name and an icon for every type of file (mod,def, lnk,sym,prg). Ok they were in a folder, so there should be a possibilty to change the path for the source, but it dosen't seem as the option program can set this path. So I copied the sample files in to the main directory and erased the folder. Back in the desktop program, hey presto, there were the icons. To start the compiler (linker etc.) you click in the field where you would like to create a file, so to create the sym file of a definition module TEST you click in the row with TEST as name and in the column under SYM. I did this for all definition files on the disk, the compilation speed doesn't seem

different to the old version and then I compiled the implementation module of the main progam. Result: 4 BOMBS, probably the compiler ran out of stack, but errors like this one MUST be trapped for the compiler to be of any use. Writing the VT100/Tek4010 emulator with CCD/OSS pascal this happened to me once in 4 weeks and then I was at least using a more obscure feature than just compiling a program. Well at least I didn't have to reboot.

After this experience I decided to write a small program of the 'Hello World' type to test the rest of the system. To create a new file in the desktop you have to start the editor by double clicking the editor icon, this works but the desktop does seem a bit unresponsive to the mouse button. The editor does have more functions than the old one and it does create a proper end of file now even if the eof marker isn't on a line alone. But otherwise it still is utterly useless except for correcting errors, my god have they never seen GST-Edit? The cursor movement and delete functions are slower than my terminal emulator on a 9600 baud line using VM/CMS on an overloaded 3083. I wonder how they delete, bit for bit perhaps? Leaving the editor is still funny, if I remember correctly the old version always stoped saving a file, now you have to save the file salect abandon and click cancel on the file selector dialog that pops up then.

Otherwise it is quite straightforward to compile and link a small program. When you leave the editor you click under prg and it automaticallys compiles and links the file. To run it, you have to select Execute Program from a drop-down menu, TOS or TTP programs can't be started this way because there is no way of renaming a file from the desktop.

Summary: well I haven't done any serious work with TDI's Modula and as long as the desktop dosen't get better I don't intend to. TDI do have good ideas, they are just implemented so bad I can't belive it (an other example the desktop itself is drawn exactly one pixel to high, that means it gets messed up every time you use a drop-down menu).

What really makes me furious is that the compiler itself is probably very much the original multipass compiler used for work on the Lilith computer at the ETH Zuerich and of all adaptions of that compiler TDI's is the worst.

The original compiler ran on PDP-11 with RT-11 and two friends of mine fixed it to work with RT-11 V0.5, except when fiddling with the actually kernal of the compiler it never died on them!!!! I know this is rather destuctive, but this product is buggy and unfinished, but you have to pay money for it and I think you should know what to expect!

II Key caps

As I said, we are using the ST's mainly as terminals and this leads to one problem: we would like to use a US querty keyboard layout (if you have ever seen the german keyboard you know why). The general distributer in Switzerland flatly denied even the existence of different versions then what we get here. Loading a different keyboard table is no problem, but if possible we would like to avoid sticking labels on the keys. Does anyone know if you can get sets of replacement key caps and has anyone actually changed them?

III PD VT100/Tek4010 emulator

The terminal emulator is finished and I will send the uuencoded executable

and documentation to anybody who asks, but I will not post 100kB worth of files
to the net if nobody wants the program (the response to my last posting was
1 piece of mail).

There have been several comments regarding the speed of reading and
writing on the ST floppy drives. One person who has looked into the
problem and done something about it has commented on it within our
internal notes files here at Digital. He has been involved in the
development of Sedt (now in Beta test), a screen editor that is a
superset of the Digital supported EDT text editor.

Exerpts from his notes follow...

.
.
.

I have spent a lot of time trying to improve the speed that Sedt loads and saves files at. By now it's getting pretty decent. I did discover that the problems indeed are the ones covered in the previous notes.

The first problem is that it's DEATH to use the higher levels of C file routines in ALCYON C. Stream I/O runs incredibly slow. I currently use the next lower level and will migrate to the lowest (firmware).

The other problem is interleaving. I bought a SUPRA 20meg disk which they had mistakenly formatted with an interleave factor of 2. Last weekend I reformatted it with 3 and saw a

marked improvement in speed. I guess that when you only get one sector per revolution it really is slow. It must be the same problem with the floppies.

.
.
.

By doing all the formatting myself and experimenting with different transfer buffer sizes I was able to greatly improve the floppy read/write times. Sedt now loads and saves files from floppies between two and three times faster than Micro EMACS. For any kind of read/write to or from floppies transfer rates drop dramatically as the buffer length increases and then flattens out around 6K buffers. After that is has a tendency to go up and down a bit because of interleave delays. From this I am 100% certain that the performance problems are caused by poor interleaving of sectors on the floppy.

Actually, with a small compiler hack, you *can* auto-allocate stack
space. The trick is that while in general you can't restart, there
are specific instructions that can be restarted. tstb is one such
instruction. The hack to the compiler is to make it generate a

tstb in the function entry code to access the lowest stack address
that the function will use.

I have heard people claim that there is enough information around
after a bus error (or address error) to restart most instructions,
if the bus error handler is willing to be clever. However, I haven't
seen any actual code... Anyone know if this is true? If so, what
are the instructions that can't be restarted?

A reasonable attitute, but remember that both the Amiga and Atari were
intended to be affordable machines. To this end, they contain only those
things that were considered to be needed - no 'it sure would be nice...'

type goodies.

[]

An Atari dealer has kindly shown me a note from Atari, explaining
how to fix the high-pitched whine the 1040 makes. More on that
in the next posting. Here I want to report on some other hardware
related things I found when I finally opened the box, and a story
about lightning, with a moral.

I have an Atari 1040STf, and the mother board says "revision B".
It was shipped in April, 1986.

A few days ago I left home, and unplugged the computer system from
the power lines as usual. But the computer was still connected to
the phone line, through the modem. I came back after some heavy
thunderstorms, and the modem was dead. Investigation revealed that
the computer itself was also damaged: the 1488 chip that drives the
RS232 output was blown, and inflicted 12 volts on the mammoth 68901
MFP chip that drives it, a 5V device. Luckily, the MFP is OK.

The moral of the story: Put surge suppressors on the phone line,
and unplug that line too in inclement weather.

What I also found inside the box:

The CPU and RAM chips are NOT socketed. Only the ROMs are.

There is no socket for the (future) graphics chip, and only about
a half-inch space above the CPU (and under the metal shield)
for piggy-backing (and heat dispersion). (I have used my unmodified
1040 for hours on end (with the disk drive mostly idle) in 95 degrees
Farenheit, with no ill effects. To be extra safe, I _have_ later
installed a very small fan above the middle of the grating area on top,
blowing _up_. It is very effective. I use it only when the weather
is very hot.)

In the middle of the back area, between the disk drive and the power
supply module, there is an empty spot about 3 inches square. It was
clearly intended for the RF modulator, and some enterprising soul
could market a modulator to plug in there! (There is a hole in the metal
shield (but not the plastic case) for the RF connector, and a row of
holes in the PCB in the "south" end of the area). I am still mad at
Atari for promising the modulator and then backing out. Could the reason
be heat? RF emissions? Cynical marketing policies?

There is hope for those who wanted a composite video output, though:
in the same space intended for the modulator, there are traces in the
PCB, plus markings such as "R110", for 4 resistors, one capacitor and
one transistor. It seems to be for an emitter-follower buffer, with both
input and output connected to the video-jack area. Maybe somebody reading
this can tell us what it does, and the values of the components (by reverse
engineering or by an unbelievable act of corporate openness :-).
(Somebody told me that an MC1374 chip can be used to convert RGB to
composite. Experts: any comments?)

If you don't install a modulator inside, the space may be useful for
other add-ins (a FP coprocessor is my favorite dream). Unfortunately,
the space is sliced horizontally by the metal shield, so that there is
little more than a half-inch above and the same below.

Now a plea: Does anybody know where I can obtain the National Semiconducters
FP chip, the 32081? Price? Documentation? (This chip HAS been used with
the 68000, namely by Digital Acoustics, in their "Dtack grounded" add-on
boards for Apple]['s.) (Alternatively, we may have to wait for the "TT",
but when? How many $$?) (The 68000-32081 combo is not that much slower
than the 68020-68881 (or the VAX...) (I only count orders of magnitude),
and should be much cheaper (?). The only real advantage of the TT will be
the possibility of running the 68020 (number crunching) and the 68000
(I/O) _simultaneously_.)

Another plea, to Megamax (I wrote them twice but no answer): Does the
source code offer (for $50) include the FP (assembly-language) source?

Summary: It's official and easy

[]

Atari has issued a technical note to its dealers about the high-
pitched whine in the 1040. I hope I am not stepping on anybody's
toes in posting this here.

The whine is at about 16 KHz, which most people who grew up with TV
cannot hear. I love the SM124 B/W monitor because it's silent (35 KHz
scan rate), but the whine from the computer still bothered me.
I thought it comes from the main power-supply, but the note says it's
from the circuit around the "converter" chip on the mother board (U62).
This chip makes negative voltage from the positive (using an oscillator and
a "multiplier" rectifier arrangement?). The fix for the whine is to raise
the frequency, by RAISING the values of a resistor, a capacitor and an
inductor. The latter claim is against all my electronic instincts, but I
tried it and it works. Here is how you do it:

Obtain a 5 ohm 1/4 W resistor, a 330 pF capacitor, and a small, axial,
220 microH inductor. Take the top cover off the 1040ST (unscrew the short,
self-tapping screws from the bottom). Take the metal cover off the
power-supply module (one little screw holds it down) and remove the module
itself (two screws at the two corners on the keyboard side).
Just "north" of the power-supply-module connector you will find U62.
Locate R17 (north of U62, 1 ohm), C28 (third component on the west, 100 pF,
looks like a resistor), and L4 (east, 100 microH, looks like a big resistor).
Replace them with the new components. That's it.

There is a pair of wires, blue and red, going from the U62 area towards the
RS232 interface area. The red wire carries +8V or so, relative to ground.
The blue carries the negative, and I measured -7V on it after the fix.
(I expected -12V, but 7 is close to 8 and the computer works fine...).
If you don't get good negative voltage on the blue wire, relative to
ground (not the red wire), you may have stopped the oscillations in U62.
Try a different L4, perhaps?

     I have been hacking away at trying to discover the workings
keyboard and system clocks since I was interested in battery-backing
the keyboard and having it maintain my time. Even though most of the
facts in this article may not be new, I thought I would summarize
what I have discovered since others seem to be interested in doing this
as well.

     The clocks:

          There are two clocks in the ST. One of them is the
intelligent keyboard (ikbd) clock which is maintained in hardware by
the Hitachi HD6301 microcomputer which is the keyboard chip. The other

is the system clock which, I believe, is maintained in RAM by the operating system. The ikbd clock can be read by the _xbios_ call Gettime(). This function returns both the date and the time as a single longword result. The time and the date are packed in the low and high words respectively in the format described below. The system clock (the one maintained by TOS) can be read by the _gemdos_ calls Tgettime() and Tgetdate(). Each of these calls return a word (16 bits) and each word is packed in the same format as for Gettime() which is described below:

```
     TIME
bits    0-4 (inclusive) :   seconds divided by 2
,,   5-8 (  , ,    ) :  minutes
,,      9-15(  , ,    ) :   hours

     DATE
bits    0-4 (inclusive) :   day
,,      5-8 (  , ,    ) :   month
,,      9-15(  , ,    ) :   year  offset from 1980
```

Since the longword result from Gettime() contains both time and the date, the longword can be broken into 2 16-bit words and analysed as above.

For example, the word (in binary)
%0000110100001110
represents August 14, 1986

and
%0101000001110100
represents 10:03:40

(Note the date is offset from 1980 and the seconds are divided by two)

The system and keyboard clocks can be set by the corresponding functions Tsetdate() and Tsettime() for the system, and Settime() for the ikbd clock. The arguments must be passed with the date and time compressed as described above.

Since the clocks run quite independently of each other, they do not have to be in sync, and unless are made so, are guaranteed to by out of sync. In fact, this feature could be used to maintain dual-time :-). The system time, by virtue of the fact that it sits in RAM and is maintained by TOS, is not maintained across resets (because my version of TOS clobbers it and sets it to some magic date in 1985) and cannot be maintained on power-down. The intelligent keyboard contains its own on-chip RAM, which is not erased when the system is reset. By keeping the keyboard powered up even when the system is down, it is possible to keep the time and date alive in the machine. Since many programs read the system clock for their time and date information, BOTH clocks must be maintained on time. However, because my

system time is clobbered across resets, I have a small startup program (posted after this article) that checks to see if the keyboard time is valid (if the date <> 1980 and month <> 0 it is considered to be valid) and if it is, it copies it into the system time. If it is not valid, it will prompt the user to enter the time and date. Calling the program with a -f argument will force it to ask you for the date and time and it will set both clocks with this date and time.

Finally some comments:

No, the HD6301 has not been through any revisions in the recent past.

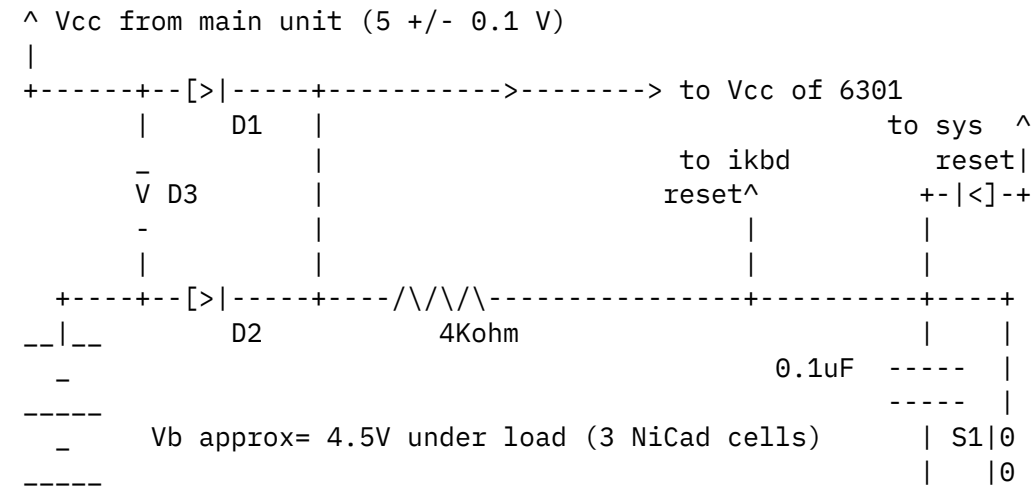
However, Atari may have had the software modified in the on-chip ROM, or perhaps the earlier versions were shipped with EPROM-med software. (Comments Neil?)

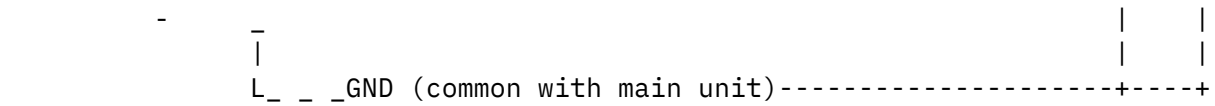
If after a cold-start your keyboard clock reads 00:00:00 00/00/80 or some date like this, it will NOT TICK (mine doesn't). To get it to start ticking, put a valid time in it (run the program given below). Your chip may be different of course, but my computer is a VERY early machine so it should have a very early chip!

Hardware:

The following little modification can be used to battery backup the keyboard clock. Bear in mind though that this mod will void your warranty and probably will require you to put the Nicad rechargeable cells in some very cramped quarters in the ST case.

****
Note, in a subsequent posting, I have sent the same circuit diagram as a squeezed an uuencoded Degas picture which is far more legible than the one below.





Diodes D1 and D2 are germanium diodes, while D3 is a 1N914 switching diode. I'm not sure if 1N914s can be used throughout, but going by the Hitachi specs I have here, it can be flakey!

The current drawn from the Ni-Cad cells is not too much because the HD6301 has a maximum operating current of 10mA, and together with the little LED provided and some of the other discretes, the current consumption goes up to about 15mA (guess) which will still give you a battery life of 3*450/15 = 90 hours (my el-cheapo Radio Shack AA nicads are rated at 450mAh).

Theory of operation: When the main unit is powered up, Diode D3 provides current to the Nicad cells to keep them charged, and D1 provides power to the keyboard, crystal-oscillator, LED and other things. Because the Ge diodes have a small Vd, diode D2 will be nearly reverse-biased and hence the Nicads will not source any current. When the main unit is powered off, diodes D1 and D3 will prevent the Ni-cads from driving the main-unit, while D2 will provide the current to the keyboard, clock and LED.

To do the mod, get hold of one male and one female header plug, some wire-wrap wire, the diodes, the resistor and capacitor shown above, an SPST switch to make an secondary reset button, and a battery holder for the Ni-cads. Make direct connections from the male to the female header plug for all except the following pins:

13 (Vcc line from main-unit)
16 (reset line)
1 (GND)

(count pins such that the key (missing pin) is pin-2)

The following is a little program that you can stick in your auto folder and forget:

------------SNIP-------CUT------------in your mother tongue now------

```

I know this is long, but if you have any knowledge of line-A stuff, I would appreciate you looking this over. Think of it as a contest. Whoever gets this working first will get netwide recognition...(or whatever will make you give me the solution...)

```
o o
 o   "The problem follows..."
\_/
```

Okay. I need some help badly! I have been trying for weeks (or at least days) to get the line A TextBlt routine to work. I need this for a project I am doing and have to finish by the end of the summer. I am writing a GEM application, and I want to write an assembly binding to be called from C to do the TextBlt stuff.

I have most of the font information I need. The font data I have organized in a raster form , and is described by an MFDB called FontActualMFDB.

Here is the C calling routine I use. The routine TypeChar is called with x and y coordinates an an integer value for the character. There are some external routines and globals variables, but they should be okay. The assembly routine that is called is AsmTextBlt.

```
          ------------------------

    VOID TypeChar(x,y,c)
    WORD x,y,c;
    {

    /*
     * effects: This routine types the character <c> at [x,y]
     *
     */
        WORD sx,sw,sh;

        sx = GetOffset(c);
        sw = GetOffset(c + 1) - sx;
        sh = Font_header.form_height;
        AsmTextBlit(FontActualMFDB.fd_addr,
             FontActualMFDB.fd_wdwidth * 2,sx,0,x,y,sw,sh,
             color,Font_header.light_mask,
             Font_header.skew_mask,Font_header.thickening,
             0,0,0,Samp_vregf_buffer,
             1024,Clip_on,Clip_x1,Clip_y1,Clip_x2,Clip_y2);
        return;
    } /* End TypeChar */

          -------------------------
```

Okay, now here is the assembly stuff. I don't really know what the Alcyon calling conventions are, so most of this is just extrapolation from other people's code. Likewise, I don't know what registers must be saved, etc. If someone can tell me why this doesn't work, or, if they can send me some working sample code, I would be ENORMOUSLY appreciative!!!!!!!!!!

```

In article <767@ark.UUCP>, gijs@ark.UUCP (Gijs Mos) writes:
> You cannot do virtual memory, you cannot auto-allocate stack space, but you
> *can* do multitasking.

You can TOO do auto-allocation of stack space with a vanilla 68000, an MMU, and appropriate compiler support. Sun did this (I think) in the Sun-1. Forgive me if this is pedantic:

Part of each procedure setup (along with the LINK) is a "probe"
instruction (TST.B, say) that tests to see if enough stack is
available to hold the entire local stack frame plus a reasonable
number of arguments. If there is enough, the TST.B works. If there
isn't enough stack space, the TST.B will generate a bus error which
signals the OS to increase the stack. The TST instruction can be
thrown away, since nothing else depends on it.

```
     _foo:    link a6,#8         ; make room for local args
          tst.b    -208(sp)  ; ensure enough stack
          .
          .
          .
```

Of course this isn't very transparent if you are programming in
assembly language. But in that case you deserve to suffer. :->

    I got this on the STarter kit from John Franco, and I think
    it is so great (and short) that I have to post it! It is a
    RAMdisk program, written by John Harris, and done right at last!
    It is NOT a desk accessory. It has no graphics. It is just

an autobooting RAMdisk that will survive system resets!!!

It works as advertised, and the ability to survive system resets
is really nice. Unfortunately, I have had to stop using it ever
since I got my hard disk because both it and the hard disk use drive
D, and it seems to preempt the hard disk interrupt vectors for its
own use.

I'd like to fix it to work with the hard disk, but having the source
would make life much easier. Does anyone out there have the source
and would be willing to post it to the net? Or at least, does anyone
know who the author is so that I could contact him directly?

>faulty address and your back to GURU type crashes, yes?

Just because you are implementing "paging" does not mean that you must implement "demand paging". The PDP-11 had memory mapping registers but did not allow demand paging. Before a process ran you had to ensure that all the memory they were allowed to access was resident. You could do the same with a 68000. With a couple of 35ns rams and some address decoding (to map them into memory) you can implement a similar type of MMU. For system level access, you bypass the rams and physical and logical memory are the same. The OS loads the memory mapping rams with the appropriate address and dispatches the process. While in user mode, the high order bits are remapped into different physical locations (going through the MMU rams). You access something that you are not supposed to and you take a bus error. The OS kicks you in the butt and drops your process, or gives you a signal with the caveat that you may not return to where you took the signal. Others have already commented that with the appropriate code you really can take bus errors for stack accesses and recover, as long as the access is at the beginning of the routine to "feel out" the size. This is paging, but the pages must essentially be preloaded. During another process, there is nothing that prevents just a portion of your program being swapped out, but it isn't necessary to swap it all out.

    Enjoy...

I have been using the Micro C-Shell (v2.61) for a few months now and for the most part agree with the previous comments about it. It is a good product and is worth the cost. The features closely mimic the features found on the "real" computers at work, so it is easy to get it to do what you are familiar with in more sophisticated

environments.

One aspect that I do not like very much is that it has does not very well handle the initiation of GEM programs. As long as you are executing TOS or TTP programs (i.e. ASCII terminal oriented), all is fine. In order to run GEM programs, you must issue the command in the form:

```
gem <command-name>
```

The shell seems not to want to look for .PRG files when it is looking for commands and will not, on its own, perform the setup required for the GEM program to operate. It would seem that the gem command was added as an afterthought for ST use. Making the user select explicitly which programs will be run with the mouse and stuff makes it easier for the shell.

Not intuitively obvious is the fact that command-line arguments are NOT supported. Not a BIG deal, but it means that I do not immediately have the ability to call my Megamax editor with the names of files to be editted. Annoying, but fairly easy to work around.

To solve the problem, I wrote myself a program called "gemrun.tos". It operates seemingly identically to the gem function of the shell, but additionally passes the arguments to the system when doing the EXEC. Of course, it must be read fron the disk, so it is a bit slower (on floppies) than the standard function that it replaces.

Another anomaly I have found is in the handling of the "no match" situation on wildcard file specifications. Unlike the true csh which will eliminate the pttern word that has no match, Micro C Shell is more like the Bourne Shell in that it leaves the unsubstituted pattern word in the argument list.

>be in when it was restarted.

Close. Actually, one of the processors is set-up as the "run" processor,
and the other as the "fault" processor. The run processor executes all
normal program instructions, and has its bus cycles terminated with a
DTACK*. If a bus cycle faults, the BERR* signal goes only to the fault
processor. It then issues a "relinquish and retry" (BERR*, HALT*, BR*) to
the run processor which immediately terminates the "faulted" bus cycle,
saves the access address internally for later use, and issues a BG*. The
fault processor, upon receipt of the BG*, issues BGACK*, and releases BERR*
and HALT*. Then, with the aid of a little external glue (address latches,
etc), the fault processor fixes the memory image at the faulted address, and
releases the BGACK* line. The run processor will rerun the faulted cycle
using the same address, data, control signals, etc.

Actually, with this method, even a very complex management scheme can be
designed. And, with the price (1000 pc qtys) of 8 MHz 68K's being about
1/4 that of 68451 MMU's, the price *disadvantage* of using a fault processor
is almost non-existant. (remember that all mapping circuitry will have
to be added). Also, assuming the mapping can be made sufficiently fast, this
method has some neat advantages.

>I have a hardware question about Atari 1040ST's: Does there exist an
>Ethernet interface for this machine? And if so, what software is available?

There is a company called Logic Replacement Technology, in England, which
has announced what they call an Etherterm, which is in fact an ST520
with an Ethernet interface: their blurb is below. I called them, and
they say that it is currently not possible to use the thing as a normal
ST, but they are thinking about it. They are also thinking about the
use of the 1040ST, where there could be a physical problem in fitting
the interface into the ST.

Another British company, called Software Punch, offers networking (both
simple rs232 and ethernet apparently), but I have no definite
information yet.

Herewith follows LRT company blurb: usual disclaimer, although we have
bought quite a few of their Ethernet-VME boards and they work.
<
EtherTERM is a low-cost windowing terminal (995 Pounds Sterling) with
integrated TCP/IP networking protocol which can be connected into an
Ethernet. It is capable of opening multiple shells on single or multiple
host computers with TCP/IP such as 4.2BSD or Uniplus+System V.
Opened shells can be monitored on up to four windows, controlled and
switched by the mouse. Each window provides vt100 emulation, with
input directed to the foreground window. The terminal supports standard
Ethernet and Cheapernet, and a local host connected via rs232 port.

Surprise! It's already in the ROMs. All you need is the program that writes a boot sector on the hard disk. We're using beta versions of the program here at Atari and if we have no disasters, we'll let it out the door.

> 2) (I forgot to check) are desk accessories fetched off the floppy or

>   should have.

I lost 2 of the 3 partitions in my hard disk within days of adding the Logikhron clock card to my ST. They sent us the source code to the clock boot program, which we're examining to find the cause of the problem.

In the meantime, there's a company called "No Solder Required" that makes a clock gizmo that I like much better. It looks like a ROM socket, and to install it you remove the U2 ROM (TOS ROM in the closest socket to the rear of the ST), plug in the clock gizmo, then plug the ROM into it. There are batteries inside it, supposedly good for 10 years. The disk that comes with it contains a program to initialize the clock and another one that goes into the AUTO folder to set the system clock at bootup.

Caveat -- there's no clearance over the ROMs in a 1040ST, so I couldn't install it there, only in a 520ST. Someone handy with a soldering iron

ought to be able to desolder the original U2 ROM socket and install this
in its place.

I don't know the price, it's called the Timesaver and the company is in
Cambridge, MA.

We did license UNIX system V. Expect to see it or something similar in
a 68020-based product.

I have found two problems in the version of make which was posted to
net.sources recently. These problems are also present in the port of this
program to the Atari ST, and the same fix can be used.
(I originally found this problem on the Atari)

The first problem is that the first rule in the makefile is taken to be the
default target to be built. However the definitions of default rules
are not distinguished, so that the wrong default target is seen.
An example makefile:

```
     .SUFFIXES:
     .SUFFIXES: .b .a

     .a.b:
          cp $*.a $*.b

     fred.b:  fred.a
```

When make is run, the following is output:

```
     make: Don't know how to make .c
```

Real make happily makes fred.b, by copying fred.a.
(I don't know where the `.c' comes from, perhaps a built in default rule?)

This can be fixed by changing the function `input' in the file `input.c'
from:

```
          while ((p = gettok(&q)) != (char *)0) /* Get list of targ's */
          {
               np = newname(p);       /*  Intern name  */
               newline(np, dp, cp);
               if (!firstname)
               {
                    if(!Is_special(p))
                        firstname = np;
               }

          }
```

to:

```
          while ((p = gettok(&q)) != (char *)0) /* Get list of targ's */
          {
               np = newname(p);       /*  Intern name  */
               newline(np, dp, cp);
               if (!firstname)
               {
                    if(!Is_special(p) && p[0] != '.')
                        firstname = np;
               }
```

```
        }
```
Note that only one line is changed, but I gave more for context since
I can't easily find the line numbers. This is a rather kludgy fix, but I am
informed that the `real' make dosn't do anything more, and a quick
experiment appears to support this!

In writing this article I also found another problem, but as yet have no fix.
I tried the makefile:

```
     .c.o:
          echo making $*.o
          cc $(CFLAGS) -c $*.c

     fred.o: fred.c
```

and got the error message:

```
     make: Commands defined twice for target .c.o on line 5
```

Real `make' allows the redefinition of `.c.o' to remove the previous one.
(This still dosn't work, even if a null `.SUFFIXES:' rule is added)

Apart from these difficulties I am very pleased with this make,
and would like to take this opportunity to thank both the original
poster, Neil Russell, and Jwahar Bammi, who ported it to the Atari.

```

It's a nice idea in general . . . but not on the ST. Address
timing is *so* critical that running the address lines through a
35ns RAM would result in missing RAS and/or CAS windows on the
DRAMs. Bad things happen.

The other gotcha is that by the time the lookup RAM can indicate
if a location should generate a bus error, the memory controller
is already comitted to the read or write cycle. You'd have to
map every unused page to some piece of scratch RAM.

We looked at this many months ago, and went a different route....

A couple of postings have mentioned programs that responded slowly to the mouse's left button. My version of Degas is notorious. When I am trying to quit, it ask's are you sure and has a little OK box. I'll click and click on that box before it responds. Then, when it does responds and puts up the regular menu, I may still be clicking furiously away and click on some other command by mistake.

Well, I remembered reading something about keyboard sequences that correspond to mouse functions in the manual that came with my computer. ALT INSERT correspond to clicking that button. With some experimentation I found that, after positioning over the OK box, if I hold those keys down for a second, when I let up, the program responds.

I just thought I'd pass this on for anybody who has any program with this little glitch in it.

Regards,
Carl Weidling

A compiler that substitutes for parameters within either kind of
quote will violate the current working draft of the X3J11 committee
of ANSI. The Reiser pre-processor (used in most UNIX systems) does
do this substitution. It is safest not to write anything that would
be treated differently by these interpretations.

I am trying to write a program which will create a directory(folder), if it does
not already exist. I've tried to use   Fattrib (filename, 0, 0) to tell
me what type of file it is (or -33 if not found), but it returns -33
whether the folder exists or not. In looking more closely at the Lattice C
manual, I find that all the arguments to gemdos() are integers (32 bits),
and that all char & short function arguments are expanded to int.
But according to ST INTERNALS some of the gemdos args are supposed to be
words (16 bits). Has anyone figured out how the gemdos() [in Lattice]
sets up its arguments for Gem? Help!

>etc), the fault processor fixes the memory image at the faulted address, and
>releases the BGACK* line. The run processor will rerun the faulted cycle
>using the same address, data, control signals, etc.

As I remember the paper (though it may very well mean the same thing - I'm

not an expert on 68k pins - this may be more understandable tho) - when
the "run" processor attempts to perform a memory access that will fault,
it is HALTED in the midst of the access instead of bus error'd. Then the
"fault" processor wakes up, examines the state of the various control
signals, and stuffs the proper page "underneath" where the "run" processor
is accessing. Then the fault processor turns off HALT to the run processor,
and goes back to sleep. The run processor then merely finishes the access
(possibly a longggggg time later). The cycle wasn't interrupted at all.

>Actually, with this method, even a very complex management scheme can be
>designed. And, with the price (1000 pc qtys) of 8 MHz 68K's being about
>1/4 that of 68451 MMU's, the price *disadvantage* of using a fault processor
>is almost non-existant. (remember that all mapping circuitry will have
>to be added). Also, assuming the mapping can be made sufficiently fast, this
>method has some neat advantages.

As I remember it there are two major disadvantages:

1) the circuitry is likely to use up an awful lot of board
   real-estate. And if you don't think that's a problem, take
   a look at a MVME117 or 131 or one of our CPU boards one day....
   (talk about stuffed!)
2) During page fault handling, the run processor is hung.
   That means, for instance, while the fault processor is spending
   it's 50 some-odd milliseconds trying to read a page in,
   the run processor is missing all interrupts, unable to task
   switch, unable to do *anything*... In a paging system, being
   able to run another task while a page fault is being handled
   is essential for any reasonable level of performance.
   If you ever started to thrash, the run processor would hardly
   ever run.

It was a neat idea, and a few machines were built, but I don't think that
the result was very useful when compared to a machine with a "real" MMU
(that is, *not* a '451).

Greetings,

As some of you will remember, I purchased 3 weeks ago a copy of I*S Talk. I informed you of how it did NOT run and bombed all over the place. Well, after having sent the program to B.I. 3 weeks ago, and 4 phone calls, I have some info to say.

First of all, B.I. was AWARE that their ENTIRE first shipment of I*S Talk did NOT run. Their head of Costumer Support admitted this to me today. They just decided to ship it, and allow all the registered owners to UPGRADE to a working copy. Now, you tell me if that is not slimy. The WORKING version is scheduled to be released in 2 weeks, and will be shipped to ALL I*S Talk owners who have registered their products. Now, that's terrible.

To sell a product with bugs in it, I hate, but can see. But to sell a product that just doesn't plain do what it is advertised to do, is an outright ripoff. Isn't there some sort of Costumer Protection Plan or organization out there to prevent this same happening? What about Atari, Neill? Do you guys care of what is happening out there? Tramiel claims that the only program he ever uses on the ST is a program by the SAME company I am talking about. This isn't some small in-house software hack them company. This is just about one of the LARGEST ST dedicated software company. Is this a sign of things to come?

I was also told by the same person, that Degas Elite is still 6-8 weeks away. And Paperclip Elite, you will be lucky to see it by X-Mass.

Do NOT buy I*S Talk. NONE of the copies available at the present moment WORK correctly. They all suffer the SAME problems I mentioned before.

BTW, I met the writer of Final Word from Mark of the Unicorn this week. Do NOT expect many new enhancements for the ST or a GEM version of that program. He said after writting version 1.7 for the ST, he doesn't feel like doing anything else. He prefers IBM. He just finished version 2.0 for the IBM. If I was you, I would shop elsewhere for a good wordprocessor. Also, I heard that Microsoft's Write is at a suggested retail of $129.95. It supports multiple fonts, and proportionally spaced fonts. It will also support various laser printers, like the canon. The version ported to the ST was Word Version 1.00 from the Mac (Does that mean they took extra care in porting the bugs too? :-).

BTW, you guys who keep talking about the internal keyboard clock card. I hate to tell you, a company has had it for sale for about 2 months now. Cost $49.95 suggested retail. Check your local dealer. It consist of a

pair of rechargable batteries that plugs into the keyboards chip. They recharge when the ST is on, and keep the chip running when the power is down. Easy as Pie.

For those who use OSS Pascal, I had a long talk with their head of costumer support and one of their cheif programmers. They recommend anyone who is serious about OSS, to download the TECHNICAL NOTES from their BBS. He also mentioned to me that you are looking at POST-X-MASS for a new update. (Version 2.00) This version will have a new manual and extra GEM calls. They are very small, and he described me that their hardware consisted of two 1040's. They are number 10 of the software best selling list.

Bye for now,
Rick Flashman

Summary: Various Cheap modems

I have tried a few cheap modems lately and have found the following:

The GVC modem has problems with reliability. The first one I had would overheat after the 1st hour. An auto answer modem which can't be left on 24 hrs./day is not much good. You'd have to turn it on manually to answer the call just before the call was made. My 2nd GVC just died outright. I have no idea what happened to it. It is going back to the manufacturer shortly. That's 2 out of 2 modems failed.

The Tandy 2212 is wonderfully reliable. Did I mention that the signal quality of the GVC mentioned above was maginal and it had data-errors consistently at

11200 baud for uploads thus limiting me to 300 baud uploads? Don't expect all cheap modems to have adequate signals. The Tandy modems seem to have excellent signal quality (I borrowed one before and bought one later, so they have had 2 out of 2 winners -- the opposite of GVC). The command system in the Tandy is BETTER than Hayes. It is simpler than Hayes (i.e. not Hayes compatible if you are a true invalid) and maintains the last number for redial. IF you buy it on a sale you have an excellent modem fairly cheap.

The USR Password is a Hayes compatible with an excellent reputation. I tried one and almost bought it. Signal quality is good. The only slight drawback I *think* it had (memory a bit poor on this point because I tried a few modems) was that it had to have its commands entered in upper case only. This is common and I think even the real Hayes 1200 baud had this problem. Strange in the Hayes when you think about the cost.

The Avatex 1200 seems to have good signal quality (I haven't tried 1200 baud uploads yet). It requires commands to be entered in Upper Case only. You cannot use the Hayes +++ command. Forced disconnect, baudrate selection on originate and voice/data control are all manual. Baudrate selection is automatic on Auto-Answer, which suits me fine..

First of all, thank you for all the replys on getting STKermit (there really are some people out there)!!! I got all the many parts with no problem, however, I can not get any of the UUE files to decode correctly. I compiled the source for UUdecode and I can't get it to decode correctly. The problem seems to be that the gateway adds spaces at the end of every line to make all

lines 80 characters, and I know that tabs are being expanded, too (but I don't think that is the problem). No biggee, I just needed the source.

Now, where or who can I get a copy of the source for ST MicroEmacs from?

And to answer all the people in netland wondering about the keyboard mod to keep the system time running. I am the one who posted the note, but have been too lazy to put up the schematic (that and a few bugs to fix ... the charging circuit is weak, and my mouse started to drift after the mod). But we'll get it together soon, and share it with the rest of the universe.

Mike

Subj. My comments on TDI Modula II

Ooops, you can get out of the Modula II editor easier than I claimed. Select CLOSE in the drop-down menu. The editor then saves and presents the file-selector dialog. I played around with the debugger last night and I needed only 60s to crash it, TDI what about debugging the debugger? I do like Modula II by the way and I'm just waiting for a good implementation on the ST.

Simon Poole.

>I'd like to fix it to work with the hard disk, but having the source
>would make life much easier. Does anyone out there have the source
>and would be willing to post it to the net? Or at least, does anyone
>know who the author is so that I could contact him directly?

I disassembled this ramdisk posted by Braner, and the mod you need
to change the ram disk drive to C or E or whatever is indicated below.
Here follow three lines from the original posting of this ramdisk:

D2 BC 00 00 00 12 23 C1 00 00 04 7E 30 39 00 00
04 C4 08 C0 00 03 33 C0 00 00 04 C4 2F 39 00 00 <-- change the 03
06 66 3F 3C 00 20 4E 41 5C 8F 42 67 4E 41 02 00

The C0 00 03 is the BSET #$03,D0 instruction that sets bit 3 (= drive D)
D0 is moved in the next instruction to $4C4 (the drvbits word).
So change the 03 to 02 if you want drive C or to 04 if you want drive E
to be the ramdisk.
Hope this helps.

Coming in on this a little late, I would like to add that there is
a program that runs on the PC that reads and writes many different
alien formats (275 is what they advertize). Included is the ST
format. Name of the program is XenoCopy II, from XenoSoft in
Berkeley, CA. $79.95

The mod just posted is not the best way to get the keyboard chip to keep the
time. Youy must keep the reset pin high on the chip when the power is off, or
the time will just freeze. To do this, I have used a nand gate circuit.
Adding another reset button is silly (in my opinion) when it could be done with
the proper circuit. Also, the reset line must go low when you hit the rest
button, or the keyboard will not work correctly. I will post the mod this
weekend, so all can see.

And yes, their are two different versions of the chip, I have had two in my
hands, one says V01 and the other says V02. To me that is two different chips
Perhaps the little chip on the keyboard is different, but the appears to be
a simple buffer (the little chip by the 6301).

    There have been several requests on the net for computer aided translation from Intel 8086/88/80186 processors to Motorola 680XX processors. I know of someone who developed software tools that accomplish this, and has been using them very successfully for the last two years. The object of the conversion was a communications package running (and being developed) on an IBM PC/XT and Tandy 2000 (80186), about 20+ thousand lines of assembly language code.

    If anyone is interested in this capability, they should talk directly to: Duane O'Shay, Software 66, 3119 E. Des Moines, Mesa Az. 85203, Telephone - 602+924-0704.

    I have known Duane O'Shay professionally for about five years, and have been quite impressed with all his work that I have seen.

    As usual, I have no financial or other vested interests. These are purely my personal opinions, and do not represent my employer in any way.

Can anybody give me the definition of the processing done by uudecode so I can
implement a version on a non-unix machine? It strikes me it would be handy to
download the encoded file and decode it directly on the target machine rather
than on the Vax. That way I wouldn't have to figure out how to transfer
binary files -- which is the whole reason for uuencode in the foist place.

Wrongo, Oh Bit Breath! PDP-11s from an 11/44 on up can demand-page quite well, thank you, though rather inefficiently. I used to work for a firm called Datalogics, in Chicago, IL, which had a demand paged operating system called DURESS which had originally been written in about 1977 as a derivative of RT-11 and RSX-11D.

This operating system used all three address spaces (USER, SUPERVISOR and KERNEL) and was fully demand paged. In fact, you will find there is a service order available on the PDP-11/44 designed to correct a bug in the memory managment unit that we turned up when we first tried to port DURESS to it.

Another comment; DURESS could run proverbial rings around the available UNIX versions of that era. It made a PDP-11 look like a real machine to the user in terms of performance. On the other hand, it had a really grungy programmer interface, and a semi-flat file system (yuck!)

PDPs less than an 11/44 (11/23 through the 11/34) had a simplified memory manager which did away with SUPERVISOR space, and split I and D, which in my opinion severely crippled them.

>than any IBM machine, but we dunno when we will get one. We DO have
>the IBM-Compatibles in stock, though" When people go computer shopping
>they like to get what they buy NOW, and not wait for some non-announced
>date.
>
>Silver,
>SILVER%UMASS.BITNET

I will have to agree here, as we are also a dealer here for
Atari ST's and compatibles.

Some answers would be GREATLY appreciated, as the number of calls
I've gotten recently on the 1040ST has doubled and tripled
because of the advent of wonderful software like Music Studio,
the Michtron software, OSS Personal Pascal and magazines like "STart"
by Antic and "Atari ST Disk & Magazine" by Compute (wonderful
creative name for a magazine, eh?)

Anyway, WE NEED ANSWERS!!!! Please, Neil, if you can help us, please do.

As Silver said, we are losing sales to PClones because people can SEE the hardware.

I have two basic questions:

1) Availability of hard disks (20 meg)

2) When is the IBM emulator due. (I need a realistic date -- it is totally unfair to lead people on if the product is 6 months away. If it will be 6 months, for Christ sake, SAY SO!)

I hope Atari understands this as positive enthusiasm for a spectacular product and not as something negative.

PEOPLE WANT TO BUY ATARI'S, I TELL YOU!

I WANT TO SELL THEM!

Aloha from Waikiki,

Jonathan Spangler

Keywords: fast but noisy

Well, I finally broke down and got an Atari hard disk for my ST. The good news is that it's fast and has lots of room. Programs that take 20-30 seconds to load from a floppy load in a second or two from the hard disk, so there's no more sitting there twiddling your thumbs waiting for it to read the files.

The bad news is that the disk is very noisy. I didn't notice it so much

when playing with the demo machine at my dealer's, perhaps because there was more background noise there. It's loud enough to be bothersome, though, so I'm going to experiment with some acoustic shielding for it. It's not possible to just move the disk farther away because the cable is very short, and using a longer cable is not recommended.

Here are a few other details on the disk. First of all, if you don't have TOS in ROM, forget about using the hard disk. You cannot boot from the hard disk either -- you need to load the device driver from a floppy.

The hard disk is divided up into "partitions" or "logical disks". You can have up to four of them, and you can configure their sizes. However, once you've configured the partitions, you can't reconfigure them without erasing the disk.

The hard disk driver seems to be hard-wired into using disks C, D, E, etc. I haven't been able to get the hard disk to coexist with the Intersect ramdisk because of this.

If you need more than 20 MB, you can connect up to 8 hard disks up to your ST at the same time. But there are limits on the total number of directories you can have, and the number of files that can appear in each directory. The manual has a whole page full of warnings about the various restrictions.

I just bought a db25->centronics connector to hook up my ST to an old Seikosha GP-100A printer (I believe it was also marketed by Commodore under a different name...this is the printer with a one dot print head).

Unfortunately, characters sent from the ST arrive ddoouubblleedd at the printer. This printer works correctly with other computers...is there something slightly out of spec about the ST printer port, or have I simply missed something?

Thank you for any help,

I think the Avatex will disconnect if you drop Data Terminal Ready. This can be done in software so need not be manual. However it cannot be done by typing on the keyboard while on-line, as I presume can be done with a real $350.00 Hayes. The Avatex will also drop back to command mode if you lose the carrier, which is the most usual occurrence when you log out of your host system.

On the other hand, if anybody should be sending binary files or encrypted text, they might find their Hayes not the best choice for the very reason that there are data strings that will dump it back into command mode.

All in all, I remain VERY pleased with the performance of my Avatex, especially considering the price of $80.00 that I paid for it.

There are rumours abounding of a soon to be released 2080 ST, with
2 Meg of RAM, built-in floppy, a detachable keyboard (yeah!),
a port for an expansion bus, possibly a higher resolution monitor, and
support through the DMA port for the yet to be announced Atari Laser printer.
Price: uncertain; availability: Christmas ?

All of this sounds marvelous, but my question is: will the laser printer
ONLY work with the 2080, or will it also work with the 520/1040's. It

sounds like Atari is planning to use the RAM in the 2080 to drive the laser printer through the DMA, which might leave the 520/1040 owners out in the cold.

Can someone at Atari confirm or deny whether the planned Atari laser printer will work with the 520 or 1040 ST?
Neil?

     Lattice C : Help needed !

I need some code to get the overall free memory in Lattice C.
sizmem() returns only the amount of free memory in the pool, which is normaly not! the total free memory.
Have I to deal with the global pointers _mfirst, _mnext, _msize and _pool which are defined in the bindings?
I need it urgendly for a prolog interpreter. (PD)

I don't want to start a my mod is better war, and I'm only replying to
the above to clear some misconceptions that the above article might
create. I don't care whose mod is used, and if I had known that someone
was going to post a mod, I would probably not have posted mine.
To reply to some specific points raise above:

> Yes the *RESET line should be kept high, and if you look at the
> circuit I posted, you will find that it *is* kept high. Conversely,
> when you press the reset button the line will go low. Please do
> not post erroneous information.

> thought it was a reasonable solution given the constraints.
>
> BTW, the mod I posted is quite sufficient if you are going to be
> using the ST for most of the day, and will leave if off at night.
> If, on the other hand, you want to just use it for a few hours
> a day, you should think of getting larger capacity Ni-Cad cells,

and making a real charging circuit for higher charging rates.

Finally, the mod given above works. I have been using it
for about a week now.

A warning to those who would put surge suppressors on their phone lines...it is
VERY important that those suppressors be placed at the point where the phone
line enters the house (or as close as possible). Remember that surge
suppressors work by presenting a dead short to high voltage pulses...phone wire
is relatively high resistance stuff (compared to zip cord) and can get VERY
hot if a high voltage surge goes down it and is shunted to ground.

I saw some pictures in EDN magazine showing what happened to someone who
had these suppressors on his phone line...he took a lightening hit and the
phone cords leading to his modem (with surge protector) got so hot they left
black scortch marks in his rug! Phone lines without the protectors didn't get
hot at all. It probably takes a fairly close lightening hit to do this...but
not a direct hit (nothing else in the guy's house was damaged).

So if you install a surge protector...install it on the terminal block where
the phone line comes into your house...better safe than sorry.

Greg Corson
pur-ee!iuvax!kangaro!milo

P.S. I have 5 (yes F I V E) modems in my house...we have dual surge protection
installed for free by the phone company. Carbon point arrestors on the pole
and gas point ones on the service pannel in the house. I have never had any

problem with lightening.

P.S.S. Why 5 phone lines...I run a multi-line BBS system (219) 277-5825

Neil,

If one plugs the IBM emulator into the DMA port, where does
the hard disk plug into?

Does the emulator have an extension of the DMA on it? Or is there
something like a Y-connector off of the DMA port?

Does the approx. $300 for the emulator include a 5-1/4" drive?

Thanks for keeping us posted!

Aloha,

Jonathan Spangler

Help!
Does anyone understand the RTS/CTS problems on the Atari well enough to explain the problems below, and hopefully, offer a fix?

The Atari TOS has, as one of its options for the RS232 (modem) port, the option to use the RTS/CTS lines. I needed this for my modem because although the ST talks to the modem at 1200/1200, the modem communicates across the telephone line at 1200/75 (a British standard), and hence output from the ST needs to be flow-controlled by the modem which is "speed buffering" and sending at 75 baud.

My first attempt with the flow control actually worked (although see next paragraph), but had the extraordinary side effect of heavily corrupting the (non-flow-controlled) incoming data at 1200. Investigation proved this wasn't the modem, but pin 3 on the Atari (receive data) distorting the incoming signal!!!! (Yes, I know this is inconceivable, but it happens.) No distortion if TOS asked not to use flow control, or RTS/CTS is disconnected.

Further investigation revealed all sorts of other problems with the flow control. It wasn't working properly at all. Depending on the transmission rate of characters (i.e. gaps between characters versus no gaps), and whether or not simultaneous sending and receiving was in progress it would send 256 characters and then lock up, or send the first character, pretend to send the next 255 then lock up, or work ok.

The "ST internals" (abacus) book describes how TOS handles CTS incorrectly and this explains some of the symptoms, but not the incoming data corruption.

Is there anyone who knows enough to supply more detail and offer a fix?

  I discovered this little problem while writing a prime factorization
program. Consider the following fragment:

```
  unsigned long i;
  i = 16777216L;
  printf("%ld\n", i);
  i /= 2;
  printf("%ld\n", i);
```

  Imagine my surprise when the same number is printed by both printf calls! When I changed the fourth line to:

```
  i >>= 1;
```

  the program worked fine and printed the correct results. Has anyone else had problems with division using Lattice/Metacomco C? (I'm using version 3.03.04)

Summary: Still unresolved

[]

Of greater annoyance to me is the fact that Megamax-compiled programs
crash if IO is redirected from inside Micro C-Shell. The SAME
program works fine if named PROG.TTP and invoked from the desktop,
entering ">OUTFILE" into the dialog box.   This is an old problem,
but I havn't heard from either company yet. (I don't know if it's
Megamax or Beckemeyer's "fault"). Contrary to recent claims, it does
not matter (from C-Shell) if I use ">outfile" or "> outfile".
It never works - I get two balls with lighted fuses.

Any solutions? Are the companies involved going to do something
about it? The products (Micro C-Shell and Megamax C dev. system)
are generally excellent, and sales of both would gain if they'd
work together better.

Summary: I got it, but it's not the 3.X version

[]

Once more: send me an ST-formatted single sided disk and an approriate
SASE, and I'll return it with my version of microEMACS, both source
and executable (and some doc). Note: my version is NOT related to
the 3.6, 3.7 etc. versions originating from Daniel Lawrence. My version
is much simpler, on purpose. It is designed for convenience when writing
program files on the ST. It's also good for data files, and short letters.
(word processing is possible with the proff formatter, also on the disk).
The source code will also compile on UN*X, VMS, CP/M, and MSDOS.
On the ST the function keys are used, but the original control-character
command invocations also work.

     Thanks for pointing that out John. What baffled me for a while was the fact that leaving the VT-52 emulator or leaving Flash doesn't drop DTR. David Betz on BIX has a new version of BMODEM which drops DTR on exit, but it would seem that this isn't the ideal situation yet because you cannot call a SHELL from within BMODEM at this time. This limits what you can actually do from within BMODEM. David is going to write the next version of BMODEM with a Disconnect command which will force DTR low from within BMODEM. This seems to be the best idea for now.
Those of you writing Comm packages should keep in mind that there are essentially two standard methods of forcing disconnection. The first is the DTR low, which fakes shutting off the "terminal". The second is 1/2 BREAK which is from Bell 103 and 212A modems. One or both of these should always be available to the user.

...

>All in all, I remain VERY pleased with the performance of my Avatex,
>especially considering the price of $80.00 that I paid for it.

     I agree. Although I've only had it for a couple of days now, I have successfully uploaded and downloaded at 1200 baud across Tymnet which failed with the GVC. Also, I have reports that real Hayes modems are not particularly reliable either (though likely not as bad as the GVC's), so there you have it. It seems you can do better than a real Hayes modem for much less.

Can anyone out there point out what the latest version of
the megamax C package is ? I have seen the posting of
m5 @ megamax about some bug fixes, so I would like to buy
the newest version ...

m5 @ megamax ???

Thanks   Stefan Brantschen

    >and would be willing to post it to the net? Or at least, does anyone
    >know who the author is so that I could contact him directly?

    I disassembled this ramdisk posted by Braner, and the mod you need
    to change the ram disk drive to C or E or whatever is indicated below.

Thanks for the reply, but simply changing the ram disk drive number is
not enough. The ram disk program is modifying some hard disk vectors
(apparently pretending to the system that it IS a hard disk), and this
disables the real hard disk. I don't think it would be difficult to fix
with the sources, but it would require a more thorough understanding of
the code than I can get after a quick browse with SID.

Which brings up the question: Does anyone know how to get printed output
from SID? When I try to redirect standard output, it crashes, and I am
not aware of any way of printing from within SID.

An easier solution to the problem is to hold the mouse button down for a second. That way you can avoid having to take your hand off the mouse, type, and then get the mouse again.

In all the talk about various modems lately, especially low cost ones, I have been interested to see no mention of the Team Industries SMARTeam

modem. This could be because of distribution peculiarities or other things.
Anyway, I bought one at a swap meet in the SF Bay Area a few months ago.
The going price seems to be about $165 which is cheap compared to Hayes
and expensive compared to Avatek. But comparing to Avatek based on what
I have heard and read, it has a lot more in the way of features. It is
completely Hayes compatible meaning soft access to all registers and
features. It has an external speaker (soft controllable - you can shut
it off all together, leave it on constantly, or leave it in default mode
where it shuts itself off when it receives carrier. It is 300/1200 baud
(with 1200 being default) and I have had *no* problems with signal quality
in transferring many megabytes both ways (both binary and ascii). I
even had a good experience with customer service. A few weeks ago I
started having problems getting connected to a couple of BBS' and the
VAX at work when it had been working flawlessly before. I tried different
RS232 settings from the desktop and nothing changed. I tried a different
cable and concluded that the modem was bad. I called the US distributor,
they told me to send it in. I got an *exchange* modem back in 7 working
days, no questions asked. When it didn't work, I discovered that the
problem was with me and my software, not the modem. The modem never
was broken, but the company was responsive anyway. I like it.

I haven't seen this modem advertised, but it seems to be around and I'm
convinced it's a good buy. The only thing it's missing that I would like
to see is a clock, but overall, I'm very happy with it. Check it out.

Okay, here comes my next salvo of St questions...

1)   This is a strange one. I wrote a routine that works like
     graf_dragbox (Drags a rectangle within a bigger rectangle

until the button is lifted.) The difference is that I had it draw a raster image instead of a rectangle. (I am doing cut and paste stuff, and this is how I paste, by dragging the bits and stop when I PRESS the button (instead of lifting it.)) I use vq_mouse to monitor the mouse coordinates and the button state. The problem is that when I click the button, the AES queues an event. I tried just flushing the button click event by doing an evnt_button afterwards, but the event is not always a click. If the mouse happened to be positioned over a "full box" on a window, the AES would queue a window full request. So, the question is, is there any way to stop the event accumulation? How is graf_dragbox written?

2) I want to patch an Alt-Help driver into memory. Someone told me that the Alt-help vector was at $502. I figured the best way was to use a terminate and stay resident program that would set the vector, and sit around. BUT I DON'T KNOW HOW TO USE PTERMRES()! How do I find the value of the amount of memory to keep? Help!

3) I'm still looking for line-A TextBlt code. Any example of TextBlt that works will be GREAT!

Summary: Hold the left mouse button DOWN!

There has been some talk lately about slow responses to the mouse buttons.
I would like to clear some of that up.

When you press a mouse button, GEM starts a delay timer. It waits for that timer to expire before returning the mouse event to the application. During that time, GEM is checking for things like double-clicks and chords (multiple mouse buttons down simultaneously). At the end of the delay, it compiles an idea of what the user did, and returns from the wait if the waited-for condition happened.

The user can set this delay time from the Control Panel: that's what the "sleeping/running" mouse icons mean. The higher the number, the shorter the delay time.

To demonstrate this, open your Control Panel and click on the 0 box. Now go down to the keyclick box and click on it a couple of times. Notice the delay between your click and the change in the box. Go back and select 4 instead of 0, and click on the keyclick box again. The delay was shorter this time, wasn't it? The delay is the amount of time you have to double-click before GEM gives up and registers a single-click.

Now about Degas: I believe the author of Degas wrote his own dialog handler. In any case, the apparent delay time between button-down and action is a LONG time. Multiple-clicks won't help. The way out of a Degas dialog is to HOLD THE BUTTON DOWN over Ok/Cancel/whatever.

No firm release date yet. The developers of this package still have to finalize the ST version. The 8-bit Atari version has been out for a few months now.

It does use the mouse and drop-down menus. The database includes all 88 constellations and every star down to some magnitude (not sure at the moment, but lots). It includes all the planets and this past visit by Halley's comet. Deep sky objects like galaxies are also included. For every object displayed on the screen, there is a text entry that can be called up by clicking the right mouse button. A very impressive program.

Keywords: clock

~~~~~~
~~~~~~

I know everyone on this net delights in soldering arcane goodies inside their machines. This message won't please you.

There is a new way to save the time in your 520ST without any soldering or other dangerous hacking. Perfect for people like me who have been contaminated by working in the Marketing Dept.

The device is called the Timesaver and comes from a company called No Solder Required. It looks like a ROM socket with a chip buried inside it. Upon close inspection you'll notice that there is a pair of batteries somewhere in there too. According to our R&D people, this is an off-the-shelf part from Dallas Semiconductor. The No Solder Required folks added an ST disk with two key programs: one to set the clock the first time and the other to go into the AUTO folder and set the system clock at bootup.

Installation is a pleasure. Open up the 520ST and pull off the ROM in the U2 socket. Plug in the Timesaver, and then put the ROM back in. Close up the unit and you're ready to go.

Notice that I specified a 520ST. There's not enough clearance between the 1040ST ROMs and the power supply to fit this in. I'd bet you could desolder the ROM socket and put this in its place -- say, I guess there is something in this message for you hardware hackers!

The company's address:

No Solder Required
351 Mass. Ave.
Cambridge, MA 02139

No phone number or price was provided to me with the sample I got. It's been in my 520ST for a couple of weeks now with no problems. And the batteries are supposed to last for 10 years! Nice product.

When I accidently hit two keys at the same time on my 1040ST, while
using the VT52 emulator desk accessory, the serial port sometimes locks up.
It will not send and most (but not all) of the time will not receive. On
occasion, the host computer has continued to send data but my ST would not
send, but on almost all (I would estimate 95% of the time) occasions
both directions lock up. The system otherwise functions normally. The
only way to solve the problem is to reboot.
   I have never had this happen with any ST telecommunications program
other than the VT52 emulator, though I have on many occasions sat there
banging away on two keys to try and make it happen.
   It is a repeatable problem with the VT52, however.
   Does anyone know why this happens? Has anyone else had this problem
or is there something wrong with my machine? (unlikely, because all
other programs work fine.) Is there a fix for this, like a new version
of the VT52?
  Thanks...

after I sent that previous message about the VT52 locking up, I realized
that I send it out under the wrong network name-- IE "Atari" (which is
the mailing address of my users group), rather than "MCOHAN" which is
my personal address. Please do not reply directly to the previous
message, but rather use the addresses I gave at the bottom of the letter.

BTW, COMPUTE!'s Atari ST Magazine and Disk is out-- I picked up a copy
today at my local magazine store.

How about it ?

This bug was mentioned on the distribution leaflet as a KNOW BUG in Lattice 3.03.04.

If memory serves me right all factor of two divisions are converted to a shift, but the shift count is one too small; ie. /2 becomes >>0 and /4 becomes >>1

Nice Uh ?

The fault is with Megamax, not Beckemeyer. Its even more strange
because Magamax manuals frequently refer to the Beckemeyer shell as an
alternative to their useless 'graphic shell'; an even worse imitation of the
Gem Desktop.

What happens is the following.

The Megamax compiler treats the function main as a special case, and if it
sees any arguments in its function header, it generates a reference to an
external label called _initargcv. If no argumenents to main are found, then
the compiler generates a global label _initargcv in the module containing
main, and it consists only of an RTS instruction.

So the problem arises in the _initargcv in the SYSLIB library.
What _initargcv does is the following:

It initializes the argv, argc variables (At Megamax they sure don't read the
GemDos manuals: they don't initialize the **envp pointer). When the
_initargcv routine comes across an argument line token starting with
'>' , '<' or '>>' they do their own crazy i/o redirection.

The i/o redirection in Megamax works as followes:

Megamax probably didn't like GemDos' not opening a standard error file,
and therefor desided to do it themselves. GemDos DOES open standard input
and output though, even the filedescriptor numbers of those two files are the
same as in unix, (0 and 1), but the filedescriptor 2 is missing (that one
refers to the RS232 port, Sigh). If you write a short program with Megamax
that prints out the filedescriptor numbers of stdin,out and err, you will see
the following numbers appear on the screen:

     -32000

```
     -32000
     -32000
```

Now every time you do a read or a write your filedescriptor is compared with -32000 (SPEED!!!). _Initargcv will substitute the -32000 with a REAL gemdos file descriptor if the commandline from the DESKTOP (not the Beckemeyer shell) contains one of the redirection characters.

I came across this bug when writing my own C-shell, that does the io redirection BEFORE the commandline is passed to the program called. I do the i/o redirection with the gemdos equivalents of the UNIX systecalls dup and dup2, the same way i think as the Beckemeyer shell does the io redirection.

Shortly I will post the follwing to this newsgroup:

- Newly coded _initargcv to accomplish REAL io redirection, at the price of loss of the standard error channel.

- Code to catch the Gemdos kill character (^C), which is less trivial because Megamax produces position independent code.

- A prerelease of my idea of a handy C-shell like command interpreter, (in about a month from now) that will include (at least) the follwing features:

  - real io redirection
  - shell script execution (batch.ttp can be thrown away), including parameter passing to shell scripts.
  - aliasing
  - shell variables
  - history mechanism
  - real UNIX pathnames (as the backslash will be the escape character)

  -Commands:

```
  alias             define a shorthand
  cat               list a file
  cd                change working directory
  chmod                  change file flags
  clear                  clear the screen
  cmp           compare files
  cp   [-f]     copy a file
  date                   get / set  date and time
  df                     show free space on drive
  diff          get file differences
  echo [-n]     print arguments
  history                see previous commands
```

```
logout                  exit from GP-shell
lpr           send to line printer
ls   [-lt]          show files
mkdir                   create a directory
more                list a file
mv   [-f]           rename or move a file
od   [-coh]         dump file
pwd                 working directory name
read                read variable
rm   [-i]           delete file
rmdir    [-i]           delete a directory
set                 set/show shell variable
touch                   update file time & date
unalias                 undefine a shorthand
unset                   clear shell variable

- internal variables:

color               to set the screen color (now black or white)
blink               set the cursor blink rate
delay               set initial keyboard delay
repeat              set keyboard repeat speed
path           search path
home           home directory
prompt              your personal prompt
ignoreeof      control-D acceptance as logout

(the first four vars will render the control panel useless)

If anybody has additional ideas for commands and the like, tell me,
and i will include it.

(This shell is not a port of any existing shell, and was written for
the ST in the first place)

Apparently-To: rnews@mcvax

It took me some time before i realized why the code i used with other C compilers to catch the ^C Kill character wouldn't work with Megamax.

At last i found that the code the Megamax compiler generates is position indepentent, and the data is referred to using an offset from register A4.

So when a control C is typed the first thing you have to do is restore the value of a4 to gain access to the global variables.

The value of a4 must be saved so that it can be retrieved not using a a4 offset. This leaves only ta location in the code segment, which can be accessed using a PC relative addressing mode.

This is the code i use now:

```
/*
 *  Next routine is really a dirty trick to get some storage
 *  that is not accessed using a4 offset.
 */

extern _store_a4();
asm{
_store_a4:
     dc.l 0
}

KillHandler ()
{
     asm{
          movea.l   _store_a4(PC),A4
     }
     longjmp ( whereveryouwanttogo, 1 );
}

SetNoKill ()
{
```

```
    asm{
     lea  _store_a4(PC),A0
     move.l   A4,(A0)
    }
     OldKill = Setexc ( 0x102, KillHandler );
}

ResetKill ()
{
     Setexc ( 0x102, OldKill );
}
```

Several questions (using a 520ST):

1. Is there any way to read the cursor keys from a BASIC program. From what I've tried, they appear to be somewhat 'local', except that the BASIC editor uses them.
2. Again, the cursor keys, but this time using the VT52 emulator. I signed onto a VAX and got into full screen edit and found I couldn't move around the screen. What can I do?
3. Can I set the function keys? How?
4. I have Haba-Hippo C and BASIC. I want to use random disk files (or indexed, like BASICs 'random' file). I would prefer to use a

compiled program. Is there any description of using random files, generally?

  If someone could answer or point me to some inexpensive information (I can't afford the $300 Developer's kit).

I VT100 emulator
The next 5 postings will be the uuencoded executable and the documentation
for my VT102/Tek4010 emulator. It is rather big and uses a LOT of memory,
actually there is some dead code in it which is of no use right now: the
primary decoding of 4105 commands is already done and is just waiting for
for me to finish it.

Thanks for all the requests for the program, I haven't decided yet if I
should make the source available, it's written in CCD/OSS Pascal with a bit
of assemmbler and is very long (last count: 218 kB). I do intend to support
the program and any bugs etc. will be fixed as soon as possible.

II TDI Modula II
I know my remarks were rather drastic, on the other hand I did want to provoke
responses. If this release had been the initial version I would be quite
pleased, but TDI has had nearly a year now to work on the program since the
first version and I just think it could be better. There are worse firms!
(I just forgot the name of the manufacturers of that database program for
the ST which loses records at random)

III Headers on my mail

Would some kind soul tell me if this kind of header is better?!

Simon Poole

~~~~~~~~~~~~~~~\ lineater \~~~~~~~~~~~~~~~~

i found what i believe is a bug in the megamax C preprocessor...

```
     if( a == b &&
#if FRED
     c == 'B' || d == 'E' ||
#endif
     b == 'b' || d == 'e')
          some action;
```

causes megamax to give the error:

```
     c == 'B' || d == 'E' ||
error in constant expression
```

however

```
#if FRED
     if( a == b &&
     c == 'B' || d == 'E' ||
     b == 'b' || d == 'e')
          some action;
#else
     if( a == b &&
     b == 'b' || d == 'e')
          some action;
#endif
```

compiles correctly

its a megamax C problem, uCsh is using the Force call to 'steal' i/o
handle 1 (stdout) and force it to a file, this works fine as long as
the 'redirected' program only uses Fwrite to do the output. sadly
the printf routine in megamax C does not, hence the the 2 bombs.

the worst news is that there is no fix for it (except from Megamax
hint...hint...) i had to leave redirection out of uEmacs 3.7 because
of it. i spoke to some people at atari about this and they were not
sure that DRI C's printf would fare any better.

The September issue of Analog has an article called Format+. It is a
Basic program which patches the ram verion of gem so that the disk
formater works differently. Disks which are then formated and used with
the standard gem perform io at double the speed of the normal formatted
disk. The transfer rate is near the theoritical maximum. I haven't
actually tried it yet but will let you know what I find out. /bill

I had one failure in capability of an Avatex 1200 bps modem that I'd like to share with the net. The Avatex was unable to complete a text file transfer from the ST to a VAX, using Kermit. When the Avatex was replaced with a Hayes Smartmodem 1200, the file uploaded with no problems.

For almost 2 weeks, the Avatex worked fine for interactive modem communications. It's a minor annoyance not to have a speaker to monitor for busy signals (although a jack for a spare telephone is provided). The Avatex runs slightly warmer than the Hayes, but not excessively so. I have line noise problems when dialing into work with the Hayes; the Avatex had the same behavior. When dialing BBs with no line noise (based on use of the Hayes), the Avatex also performed flawlessly.

So, no problems: Hayes performance at 1200 bps with an $89 price! That is, until I tried a text file upload from home to the VAX at work (520 ST, 1 megabyte memory, PC InterComm terminal program at home). Using Kermit, the file transfer started, but then just stopped (in one case, after uploading 2 blocks, in another, after 7 blocks). It's as if Kermit was waiting for some kind of handshake from the Avatex, but never got it. Making no other changes, I switched from the Avatex to the Hayes, and the entire text file uploaded correctly.

Anyone else seen this behavior with an Avatex modem?

By the way, the new model Avatex (100 % Hayes compatible, approx. $130) is available. I *THINK* it has a built-in speaker. I wonder what else it does to justify an almost-50% increase in price!

That's right. On the other hand, being unable to restart a faulted
instruction (in the general case) only means you can't do demand paging,
or similar schemes where you want to pretend memory is always there when
it sometimes isn't. The inability to do this is a wart, but it does not
preclude doing useful things like running Unix. This message is being
typed on a PDP-11/44 running V7, which doesn't do virtual memory but is
still a fine system if you don't want to run huge programs. The MMU on
the 44 can actually do demand paging, although it's not clear that it's
worthwhile given various complications, but V7 doesn't use it that way.
Relocation and protection is all you need to run a multiprogramming system
simply and well.

The following information is the ST RESOURCE portion of ANTIC magazine
for the month of september. The complete TOC for this issue can
be found in net.micro.atari8 for those that are interested. I have
posted only the parts of interest to the ST community in this news
group. -Kit-

September 1986 ANTIC TOC
Theme: Weather

page article

**********THE ST RESOURCE**********

54 ST WEFAX DECODER
This is the software program that you will need to be able to convert radio signels to information your ST Atari can use to display weather pictures. You will also need the WEFAX interface described on page 24. NOTE: You will also need an MC68000 assembler such as the one included with the developers kit or the one from Metacomco or Haba Hippo C assembler. You may have to fine tune it to work

with any besides the one that comes with the developers kit.

I talked to a salesman at a computer store near Boston which sells lots
of ST's/software. He said that customers have been complaining about
I*S Talk having major bugs and some brought it back demanding a refund
(which was granted.) He also told me that he bought I*S Talk for his
own ST at home, and found problems just like what Rick Flashman described:
IE Cut+Paste bombs the program etc. He was quite disappointed, as this
program would be absolutely GREAT if it worked properly-- which it
doesn't.   Batteries Included had better get their act together if they
want to keep their reputation in one piece.

I just heard some interesting rumors.

1. The IBM emulator is finished and is going into production and should
   be out by X-Mass at a price of $300. Plugs into the cartridge port.

2. The Atari TT is going right on schedule and should be announced and
   shown at COMDEX in November. It is a 68020 based system with 4 megs RAM.
   It also supports a 1024x1024 resolution screen.

Questions for Niell and others:

1. I heard that the IBM emulator does NOT support graphics. Will it ever?
   If it does, when?

2. Does the TT run UN*X? I do know that Atari DID liscence it (UN*X).
   Is it an upgrade for the 1040/520 or is it a separate machine?
   What price range am I looking at? I heard that it's release date is
   January, how correct is it?

Rick Flashman

BTW, on I*S Talk, I finally got in touch with Batteries Included. They
told me that the programmer is WORKING on fixing *my* copy. I dunno what
they are up to up there, but they said that they would ship the fixed version
back to me this Friday.

Inasmuchas the Mac ROMs are rather like the IBM PC BIOS (or, better,
what the BIOS should have been), isn't expecting Apple to license their
sale rather like asking IBM to sell its BIOS separately to clone makers?
This "product" leaves a bad taste in my mouth, if only because the producers
took the easy way out. Far better it would have been to reverse-engineer
the ROMs from the programming interface specification. This is a lot harder,
granted, but it also avoids many of the hassles that have been described in
the media.

I found that there is a great difference on which underground
the ATARI is located. On a metal-table the ATARI gets less hot
than on a thermical isolating material like wood. There is real
a great difference. An alu-plate of about 50 x 50 cm under the
ATARI will be enough to put the heat away.

This may/may not be the place for it, but I've got a modem problem I hope some-
one can help me with:

My friend has a Datec 212SB modem with the following pin-outs (shown connected to the modem port of the ST):

```
ST             Datec
--             -----

GND ----------- GND
TXD ----------- RXD
RXD ----------- TXD
RTS ----------- CTS
CTS ----------- DTR
SIG ----------- SIG
DCD ----------- DCD
DTR ----------- DTR
RNG ----------- RNG
```

The ST apparently has no DSR, and the Datec has no RTS, hence the connection above. He gets no response with XMODEM (1200 baud, no parity). Any help will surely be appreciated.

I figure not too many people will be familiar with the Datec, so if you have a suggestion, please write! Don't assume "well, someone else will answer this poor dumb slob." I need all the help I can get!

~~~~~~~~~~~~~~~~~~\ lineater, \~~~~~~~~~~~~~~~~~~~~

i'm porting uE3.7 to the ST and have run into a few problems,
perhaps some kind soul could help me. I am using Megamax C to do it.

1) when i call a sub-command using Pexec(0,STcmd,STargs,STenv)
[assume they are all char *] the first character of STargs gets
dropped or more likely the ptr is getting incremented by 1, putting
a leading blank in STargs works but seems silly

2) when the program is called from another (i.e. the megamax shell)
the cursor does not appear, if it is called from the desktop all works
fine, i have tried calling Cursconf and naming the file .prg, .tos
or .ttp but to not avail

3) if Initmous(0,0,0) is used to disable the mouse (is that
correct?) i know that you use kbdvbase to get the address of the
system interrupt routine, but what about the param struct ? just
malloc some memory before exiting the program and pray ?

A t D h V a A n N k C s E (thats not mine but it was too good not to
steal)

The rubberband line effect is easy to get on the ST. GEM supports
an XOR writing mode, where each graphic that you place on the screen
is automatically XORed with the existing pattern. As a previous
followup pointed out, this is the way to do the job.

The rubberband line is a simple call to polyline with the XOR writing
mode enabled. All you have to do is draw the line from the fixed point
to the variable point, under XOR writing mode:

    1) When the variable point selector moves to a point, and,
    2) When the variable point selector moves off that point.

Of course, this means that each line is "drawn" twice. First, to
make it visible, then again to make it invisible.

I have implemented some input routines that coordinate the mouse with
a rubberband line, and they are surprisingly fast considering that
the rubberband line is drawn twice for each individual point to which
the mouse moves during the operation.

BTW an interesting effect is a multiple rubberband line where there are
several fixed points and a single variable point. A three point system
is simplest. Just issue a polyline call supplying three points. The
first and last are the fixed points, the second has the coordinates of
the variable point.

This can easily be expanded to handle the display a closed polygon
with rubberband lines showing where the lines would be if you closed
the polygon at any particular time.

By the way, bad as they may be (in some peoples opinions), all the above
info was found in the ABACUS books and a little thought, so while they
may not be the best, they can help.

To: INFO-ATARI16 at SCORE.STANFORD.EDU
cc: BAMMI%CASE at CSNET-RELAY.ARPA
Subject: Make, Alcyon C 4.14 and libm

I had some problems with implementing the Make program posted by
Jwahar Bammi using the Alcyon C compiler from the development set.
First my version did not know about the type void and second it did not
know unsigned char (got warning unsigned char not implemented, signed
assumed). After the necessary changes in h.h everything worked fine.

The Makefile was corrupted because somewhere along the line tabs were
converted to spaces. Commands to produce targets have to start with
a tab as the first char on the line. Furter I noticed that the colon
separating target and dependants has to be surrounded by spaces. A colon
directly after a target gives funny error messages and other things.
Use -p option to see what is happening.

Jwahar, thanks for a well done conversion job.
I also have the original posting from net.sources and was intending to
do the sam as Jwahar + the Case people did.

In the h.h and readme files there are references to Alcyon 4.14 and
the IEEE floating point library libm. See below.

From h.h:
```
>#ifdef MEGAMAX
>#define void        /* Alcyon 4.14 understands void */
>#undef Fdatime        /* Megamax has it incorrectly defined */
>#define    Fdatime(a,b,c)    gemdos(0x57,a,b,c)
>#endif /* MEGAMAX */
```

From readme:
```
>   /* Pass 1 flags           */
>   setmacro("C0FLAGS", "-f"); /* change to "" if you want to use IEEE
>                   * floating point and libm instead of libf
>                   * by Default. Otherwise simply redefine
>                   * C0FLAGS in your makefile to get the
>                   * IEEE floating option.
>                   */
```

Now my questions. Is Alcyon 4.14 a newer release from the development kit
C compiler ? (It accepts void and probably unsigned char) If so, where
do I get hold of it? Any info on differences with the Development kit
C compiler are appreciated.

Concerning floating point. Where is info on libm available? Where can
I get it?
Thanks for any info again.

Steve,

     It is illegal to "reverse-engineer" the roms. In order to write your own version of the O.S. which is functionally equivalent to the original you must have never have seen actual code from the original roms. If you have seen this code you may be accussed of having stollen some of it. Phoenix Software had to find programmers who had never seen the IBM PC bios before when they wrote their bios.

John

I would like to convert my single sided drive that was bundled
with my ST to double-sided. I've heard there is a company that does
this for a nominal fee. Who is it and/or how can I do this
myself?

Most programs do use XOR. MacDraw, for instance, leaves things in OR mode
until you start to manipulate an object, then redraws that object in XOR to
allow rubber-band feedback.

However, if you look closely at a line being drawn in MacPaint, you will see
that XOR mode is NOT being used. The line is solid black all the way
through, whatever the original contents of the screen. Apparently, MacPaint
saves the original bitmap not only for Undo, but also for redrawing the
screen contents during rubber-banding. The CopyBits is carefully
synchronized to the vertical retrace time for maximum smoothness.

Another example of attention to detail (there are a lot of them in
MacPaint), something Microsoft should probably investigate.

****
****
I have a problem and perhaps one of you folks "out there" can
help me. I need an assembler for the 1040ST rather badly.
      I have a copy of the one in the "starter kit", but either
there is something wrong with it (unlikely) or there is something
wrong with the way I am using it (probably).
      Can someone out there either:
      a) send me directions (preferably pretty explicit) on how
to use the assembler I have;
      b) send me a PD assembler, preferably with (explicit)
instructions.
            OR
      c) tell me where I can find a good assembler. The only
one I have actually seen in a store costs an awful lot.

           Thanks in advance for the help.

With all the talk of the new CoCo's memory management system and the
discussions wondering why a 68000 was not used I have the following
thoughts (yes I have ONE now and again :^>)

If memory serves me correct the 68000 can not restart/resume a bus faulted
instruction. So regardless of what mkind of MMU you try to hang on it, it
can not overcome this problem. As I understand it, the 68000 does NOT
ensure the address pointed to on the stack, is the address of the fault
instruction. Therefore you can't restart the instruction and 68000 does
not dump it's micro-state, so you can't resume the faulted instruction. Is
this about right?   Motorola you out there? Guy Harris, this about the
scheme of things? Henry of UTZOO, this acurate?

BTW the 68010 fixes this.

Yes, it's an icon for the cartridge port. The developer's kit
explains how to make a cartridge that will cause files to show up in
the cartridge icon's window.

First, I'd like to thank everone who took the time to send replies.

Here is what I've found. Originally I was trying to read/write from MS-DOS
disks written on an HP-150. It seems that the HP-150 uses 256 byte sectors
instead of 512 byte like the ST. Since then, I located an IBM-PC with a
3.5 inch drive.

The IBM-PC was unable to read disks formatted by the ST. However, the ST
was able to read/write the PC-formatted disks, and the PC was able to read
the disks after they had been to my ST and back. It seems that there are
minor formatting considerations which the ST ignores but the PC enforces.

My experience, then, is that as long as the PC controls the formatting,
files are exchangable between the PC and the ST.

Is there an *easy* method to access GEMDOS calls (example: Tgettime)
from ST-BASIC. The ST-BASIC manual isn't very clear on whether this

can be done without writing some sort of assembler or C interface.

If an interface is required, would someone be kind enough to mail or
post an example.

Jim:

I believe you are confusing a "null modem" connection with a normal data
terminal to modem connection.

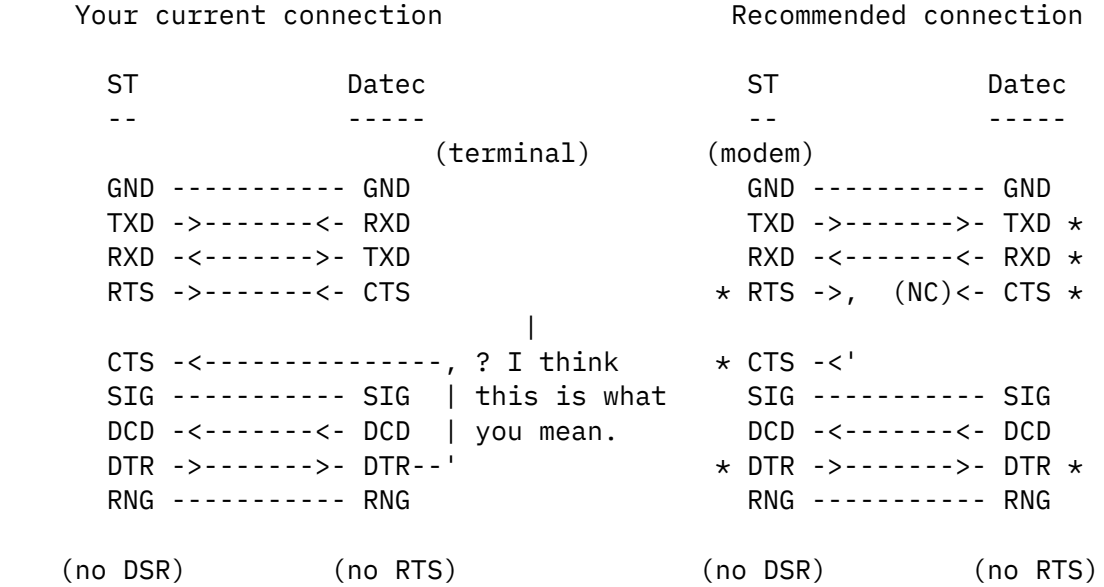
The kind of cross-connection you are using is appropriate when you are
connecting two terminals together, or a computer, which is a "smart" kind of
terminal, to an ordinary terminal. In that case you DO want each Receive Data
input to look at the other's Transmit Data output. A cross-connecting device
called a "null modem" is used for this purpose, and to cross-connect several
of the other control lines as you were trying to do in your setup. Basically,
a null modem acts like two back-to-back modems, which would have to be used if
the two terminals were not physically close enough to connect directly. But
of course it is A LOT CHEAPER than two modems, back to back or otherwise!

However, in your case, you don't have two terminals; you have one terminal and
one modem or "Data Set". And I believe that you want to connect the
terminal's (Atari's) Transmit Data output line to the Transmit Data INPUT of
the modem so it can transmit it (what else?!). Similarly, you want to connect
the modem's Receive Data OUTPUT to the Atari's Receive Data input.

Also, the ST's Request To Send output should not be connected glaring face to face with the modem's Clear To Send output. Each output on one side should go to some input on the other side. One output can go to several inputs, including one back on its own side if necessary. Since the modem apparently does have a Clear To Send (CTS) output, one possibility would be to tie that to the ST's Clear To Send output in the hope that both vendors are trying to do something standard. Tying DTR's together seems wise for the same reason. Since the modem is not a data terminal, this an input which it expects to see from the data terminal (Atari). This leaves the ST's Request To Send (RTS) dangling, assuming that as you indicate the modem has no input to receive it. If things don't work in this way, the other reasonable possibility I see would be to leave the modem's CTS line dangling and strap the ST's RTS back to its CTS input. I am reasonably sure that this will do the trick. In fact, I kinda like this better than using the modem's CTS line -- if you do it the second way, at least you KNOW the Atari will be given CTS permission if it ever requests it (RTS).

Once you have adhered to the above general rule of no two outputs tied together, the only other problem in the RS-232 "standard" is that sometimes both sides are waiting for the other to "assert" (turn ON) a signal, most often DTR and DSR. In such a case, you might have to strap a signal that you are SURE is on (by measuring it with a voltmeter!) to one of the inputs (after disconnecting that input from any other source to follow the above rule) that is waiting for a signal.

Anyway, my best guess for a workable arrangement would be as follows:



The *'s indicate pins affected by the change.

If I sound as though I know what I am talking about, don't be fooled: only the electrons know for sure!!!! Other connections are possible, as long as you follow the general rules mentioned above; in fact you may find a better one. But I hope this discussion helps you figure out how to get your setup working.

Good luck with it,

-John Sangster

In article <469@imagen.UUCP> turner@imagen.UUCP writes:
>i'm porting uE3.7 to the ST and have run into a few problems,
>perhaps some kind soul could help me. I am using Megamax C to do it.

I've just finished doing a port to the Atari with Megamax. Not entirely
straightforward. The problem with Pexec() is an annoying one. It's not
that the first character of the args is being dropped; rather, the
first character of the arg string is supposed to be the LENGTH of the
rest of the string (0-127). You can't specify a longer argument list
than that, and you have to tell Pexec() how long the arg list is. Remember,
we're dealing with an MS-DOS/CPM lookalike computer here, and the
"commandline" argument is simply copied into the new program's base
page starting at location 0x0080.

I didn't run into your other problem, with losing the cursor. I don't
know why that should happen; I get a cursor with mine. Certainly avoid
naming the file "emacs.prg", since you're guaranteed not to get a cursor
that way. I also don't know why you're using Initmous(); there's no mouse
pointer when I run emacs (is it for character input, or ...?).

One problem I ran into with porting to emacs is that calling Bconin() or
Crawcin() always return ^@ for "extended function" keys like the cursor keys.
I eventually got around this problem by calling appl_init() and appl_exit()
in ttopen() and ttclose(), and using evnt_keybd() to get characters from
the keyboard. Kind of ugly. But Bconstat() and Bconout() work fine for
typeahead detection and fast character output.

One possibly undocumented feature of the Atari's lowlevel VT52 emulation
is that it DOES support reverse field. If you output an ^[p the output
goes into reverse field; use ^[q to return to normal. Convenient! To
use it, fix up the vt52rev() function in vt52.c and add "revexist = TRUE"
to vt52open() (as well as defining REVSTA in estruct.h).

The only fix I still want to make to Atari emacs is to add a 50-line
mode for monochrome; once I've got that in place I'll submit some diffs
(probably to Lawrence, the emacs coordinator). I already hacked up a nice
Amiga version; I love that 80 x 50 line screen, and running Emacs on the
ST over the serial line as a background job on the Amiga isn't bad either...

Yours in MicroEMACS hacking,

Has anyone figured out how DaTime works for the ST, or even IF it works
(I should think that they use it int the desktop!)? One obvious bug is
that if you try to get the date, you set it (if you try to set it, you
also set it!), and the value seems not to relate to the value in the
buffer. The get does not change the buffer, and with either the get or
set option the date gets changed to some unpredictable value.

After reading bammi's comments on Fdatime() in C, it appears that TDI
based the function on incorrect documentation and didn't bother to check
it -- but if the desktop uses it, they must be able to use it correctly.

Anyone know of any books or other GEM info for Modula-2 programmers out
there? The language is great, but the TDI documentation is pretty weak.

If you decide to 'play around' with an Amiga let me give you a word to the
wise. The system tasks and the disk driver are separate in the Amiga and
the communication is not real tight. What this means is that the task may
prompt you to swap disks while the disk driver is still writing to it.
If you don't sit and stare at the disk light you will take the disk out
while the Amiga is writing to it. I had quite a number of crashes that
I blame on this. Once I 'trained' myself to not pull the disk until the
light is out no matter what the screen says crashes have been extremely
infrequent.

    I've had an Avatex 1200 hooked up to my Amiga (egads!) for
nearly four months now without any problems. My only complaint is
that there is no speaker and you can't tell if the line was busy or
never picked up (if you're a wimp you can always pick up the phone :-).

I can recommend the K-Seka package from Antic catalog as a good
assembler. It assembles in memory, so its awfully fast (somthing
like 30,000 lpm is advertised). It comes with a symboic debugger etc,
and its relatively inexpensive $35. The main problem that i
have found with it is that it does'nt have a 'include' type directive. SO
even though you can develope a bunch of utility macros, they are
not easy to include (you have to do it manually using the editor). I personally
have switched to Hi-Softs Devpak St, but i am not sure if that is available
in the US. At least i have not seen it.

I have found, by comparision with what the dialouge box produces,
that the STargs string is a counted string, ie the first byte contains
the length of the string. It looks like a documentation flaw to me.

That basically it. The 68010 uses instruction continuation to support virtual
memory and/or MMUs. When an exception occurs, some processor internal
state information is pushed on the exception stack. This allows a bus error
exception handler to do whatever's necessary to get the desired address
into physical memory, then RTE, at which point the instruction that caused
the bus error will continue, recovering at the cycle that caused the fault.
This is more efficient than the method used by some processors, which
restart the instruction from its beginning. The 68000 doesn't save enough
exception stack information to accomplish this.

Oops, I guess I spoke too soon. I was thinking about some of the programs
I had used in the past, and not specifically about MacPaint. Sorry if I upset
anyone out there.

|With all the talk of the new CoCo's memory management system and the
|discussions wondering why a 68000 was not used I have the following
|thoughts (yes I have ONE now and again :^>)
|
|If memory serves me correct the 68000 can not restart/resume a bus faulted
|instruction. So regardless of what mkind of MMU you try to hang on it, it
|can not overcome this problem. As I understand it, the 68000 does NOT
|ensure the address pointed to on the stack, is the address of the fault
|instruction. Therefore you can't restart the instruction and 68000 does
|not dump it's micro-state, so you can't resume the faulted instruction. Is
|this about right?   Motorola you out there? Guy Harris, this about the
|scheme of things? Henry of UTZOO, this acurate?

The fact that it is difficult to restart an instruction that received
a bus fault on the 68000 makes it difficult to implement paging.
However, an MMU has other uses besides paging, e.g. to protect processes
from one another, to help utilise memory more efficiently, and
to allow swapping and process duplication (a la fork(1); you can't
implement fork(1), in general, on the 68000 without an MMU).

I consider it a grave mistake not to have included even a rudimentary kind
of address remapping on the Amiga; even just an adder on the address lines
of the 68000 would have simplified the system software and allowed some
kind of swapping to be hacked.

Thomas.

I read in the 7/14 issue of InformationWEEK, and in another newspaper
(I think it was Computerworld) that Microsoft has ported the Macintosh
version of Microsoft Word to the Atari ST, and that Atari has signed
a contract with Microsoft giving Atari exclusive world-wide marketing
rights to the program. The ST version is called Microsoft Write.
   Does anyone out there know more about this deal? such as...

1) Price

2) Availability-- Previous Atari-distributed/written ST software seems
to have disappeared into a black hole! (Planetarium, CP/M Emulator,
GEM Draw,graph,paint etc., Joust, etc.) If Atari is distributing this,
I sure hope they actually DO distribute it! Any info?

3) Implementation-- both the articles I read on Microsoft Write specifically
said it was an ST version of the MACINTOSH Microsoft Word. This means
it uses windows, mouse etc. I find it very hard to believe that Microsoft
would be willing to start writing GEM programs! Is there any chance that
we can see WINDOWS on the ST?? If Microsoft is now supporting the ST,
have they ported Windows to it to use with Write? Or what are they using?

4) Is Microsoft planning to put any other software on the ST besides Word?

     The following little program (disklist.c) is a simple disk directory
lister. I'm posting it for a friend.

     The program works as follows: upon startup, it will ask you
for the name of the source drive (which it will read and catalog),
and the name of the destination drive (on which it will create a file
called disklist which will contain directory listing). Every time

the directory listing is written out, it will prompt you to insert
another disk; hitting the "yummy" button will repeat the process and
hitting the "burp" button will get you out of the program. If the
disk being listed has no name, you will be prompted if you would
like to name it. The program will descend the directory tree and list
files under the
appropriate folders. The disklist file has the following format.

```
DIRECTORY LISTING  Created on - 86/08/14  at - 21:13:46

DISK NUMBER: 001   VOLUME: utilities3

   XLISP.TOS                                          60928  86/07/09  22:24:58
   COMLSP.LSP                                          8346  86/07/09  22:28:42
   DISKLIST.PRG                                        6328  86/08/12  21:32:38
   WTERM.PRG                                           9046  86/08/03  11:38:18
   KEYCODE.PRG                                         7092  86/09/08  20:34:48
   ... etc
```

Remember to set the time correctly before running the program
or the header line will be off.

Hope you find it useful in maintaining disk catalogs.

From The New York Times, August 12, 1986, p. C5:

"In an interview in the first issue of Compute!'s Atari ST, a magazine from ABC Publications that will be on newsstands Aug. 26, Sam Tramiel, president of the Atari Corporation, says his company will introduce both 2-megabyte and 4-megabyte versions of the ST computer by the end of the year.... The company has no plans, he said, to design ways for current ST owners to upgrade their machines.

"Other projects, Mr. Tramiel said, include an 'EST,' for enhanced, ST model that will incorporate high-resolution color and monochrome graphics; a 'TT' (Thirty-Two, as in bits) computer that will use Unix-based software..., and a $200 to $300 device that will allow the ST to run I.B.M. PC software. Meanwhile, the Atari line may be redesigned to look more like the I.B.M. PC, he said...."

>

Pexex does not work exactly like the unix execve, it has to be called
like this:

```
/* if MEGAMAX, DRI etc */
int success;
/* if LATTICE .. */
short succes;

succes = Pexec(0,STcmd,STargs,STenv)

Pexec ( mode, name, tail, envp )
int mode;
char *name;
PasChar *tail;
char *envp;
```

Now your problem pops up :
the tail parameter is not a standard C string (0 terminated) but
is a standard PASCAL string, the first byte is the character count,
and the string needs not be nul terminated.

try this before you pass the string to Pexec:

```
j = strlen ( tail );
for ( i=0; i<j; i++ )
     tail[i+1]=tail[i];
tail[0] = strlen ( &tail[1] );
```

A program like emacs should have the .tos or .ttp extension.
If everything works fine from the desktop you should not worry,
MEGAMAX should.

If one names the program FOO.PRG, then default is no cursor, as has been stated by many others. Naming it FOO.TOS will turn on the cursor, but if the program also contains windows and other GEM stuff from the RSC set it will usually hang. The solution for me, where sometimes I'm using windows and sometimes just naked printf's in the same program is to explicitly turn the cursor on and off. Also, GEM will fire up the cursor where it was left last time, so I usually home it and clear the screen. Then I can keep calling it FOO.PRG. Example:

```
        /* GEM stuff */
        ....
        /* regular stuff begins */
        graf_mouse(M_OFF, 0L);  /* turn off mouse */
        Cconout('\033'); Cconout('H');   /* home cursor */
        Cconout('\033'); Cconout('J');   /* clear to end of screen */
```

```
        Ccconout('\033'); Cconout('e');  /* enable cursor */

        printf("Hello world.\n");

        Cconout('\033'); Cconout('f');   /* cursor off */
        ...
```

Then, the link is:

```
link68 [u] foo.68k=gemstart,foo,vdibind,aesbind,osbind,gemlib,libf
```

Has anybody ever had problems with malloc() (DRI C)?
Consider the following piece of code:

```
long free_mem;

struct midi_event
{ int delay;
  char midi_msgs[3];
} buffer;

main()
{
  struct event *malloc();

  free_mem = (long)malloc(-1L);

  buffer = malloc(free_mem);

/*  error handling ..... */
```

```
  printf("%ld bytes free",free_mem);

  ........
  ........
}
```

What I get is "879000 bytes free" on a 1040 with a 600k RAM disk
installed....????

Any hint?

Thanks   Stefan Brantschen

<line-munchies>

Let's try one more time ->

Hello world,

     I am in dire need of one or more examples of code illustrating the configuration process for the 68230. No matter how carefully I attempt to set it up, I can't even get a single bit to twiddle when I expect it to. I have had output a couple of times but this was when I was writing in a loop to check the timing and was NOT expecting anything to come out. The output was irregular and I was not able to successfully repeat it.
     Any or all help will be greatly appreciated.

I got no less than 5 replies to my original posting, only one of which disagreed with the above. The problem is, if you XOR, then of course any existing line crossed by the rubber-band (or "flopping") line will get a hole in it where the new line crosses. I thought I looked at a friend's Mac while doing this, and saw no such hole, but I'll check again. Here's the lone dissenter--name removed as it was private mail:

 Actually, MacPaint keeps the old screen buffer and copies it back each
 time you move the line to restore the original image. It doesn't do
 XOR--if you notice, the line always looks like it will when you finish
 moving it. Bill Atkinson has a special routine that copies his "save"
 bitmap VERY quickly to the screen for just this kind of application,
 thus the fixed window size.

So what does everyone else think of this? To me, it has the ring of truth about it.

Well, I won't point by point your point by point of my point by point (:-) but I would like to comment on a couple of the places where we disagree.

You claim that the Amiga's system software is at LEAST an order of magnitude more robust that the ST's. Thinking of the blind men and the elephant, I would like to comment that in four hours of playing with a friend's AMIGA, I got about a dozen crashs. My ST crashes about once a month, unless I have to reboot because the software I'm debugging has gone into an infinite loop.

I suspect a more evenhanded evaluation would show that they are roughly as 'competent', but the Amiga has more bugs in the multitasking area, which is more complex code in the Amiga. The sad thing here is that the Amiga, being around longer SHOULD be more robust.

I think Atari has been reasonable about bugs. The ROM's didn't come out until after much debugging had been done in RAM and make the machine boot much faster. Also, putting much of the OS in ROM is becoming traditional.

Atari has fixed (and distributed free) both of the default disk accesories, as well as Basic and LOGO. We'll just have to wait and see on ROM upgrades.

As far as 'Blessed by ATARI,' $300 gets you a lot of (not well organized (:-) system documentation with a development system. Also, the 'official' documentation is due Real Soon Now (December, I'm told) However, I do agree that the documentation I've seen is better for the Amiga. Again, spending more money should buy you more.

I guess I don't know what OS choices the Amiga gives me (other than multitasking) that the ST doesn't that I would want. I would be interested in hearing more about the advantages of all the extra code the Amiga kernel carries along.

I was suprised when you mentioned "card cages", since the last time I talked to the local Amiga dealer, he said they were still expecting that box Real Soon Now. And without that, you can't upgrade the RAM to 8 meg. As far as the frame grabbers, digitizers, and related, they can be had for any system, including the Amiga and the ST, since most are available with RS232 or 'Centronix' interfaces.

I'm not sure of the status of the coprocessor board for the Atari. Does anyone know if there is currently a 68881 coprocessor?

I guess I don't seen how the 8087/80287 can be viewed as an advantage over the 68881.

You disagree with me about the ST PD software, and I am again reminded of the elephant. Almost everything I've seen which is public domain rather than ShareWare or "preview" is available with source code. This includes Uemacs, Xlisp, at least one forth, several ram disks, numerous games and applications. Much of which isn't distributed freely is available from the author for cheap.

There are some obvious exceptions. The binaries for Megaroids are PD, but the source can only be had as printout for 25$. Dave Betz' adventure writing system doesn't seem to be available in source.

However, I suspect that I was a little enthusiastic in saying that MOST of it is well written. I guess I should say that most of what I play with does what I expect it to.

I doubt that Amiga programer's as a group are more experienced C programmer's than ST programmers.

Actually, expansion doesn't come from the initial cost difference in the Amiga. You still have to buy the expansion box (for many dollars) before you can reasonably expand the system.

I do agree that the DMA port is not the same as the Amiga BUS. It allows fast devices to talk to each other and memory without hassling the CPU. This is a win in some applications and a lose in others.

I also like both the ST and the Amiga. I could buy only one. I've got an ST.

Marty

Keywords: Fdatime Gemdos Documentation Brain Damage

The gemdos Fdatime() (function $57) is incorrectly documented in the Hitch Hikers Guide, in the original Dri Gem Dos spec manual AND in the Abacus St Internals book. I just could not believe my eyes when i realized that ALL 3 of them DOCUMENTED this function INCORRECTLY. The only document that documented Fdatime() correctly was the Gemdos Manual (the April 4 release by Landon Dyer, who is on the net - kudos!!).
The correct usage is:

```
#define Fdatime(a, b, c) gemdos(0x57, a, b, c)

Fdatime(Buffer, Handle, Set)
char *Buffer;
WORD Handle;
WORD Set;

Buffer ---> WORD Time;  /* Points to buffer containing */
            WORD Date;

Handle if a Fopen'ed file handle (open for read is fine).

Set == 0  get the file mod. time and date
Set == 1  set the file mod. time and date

The Hitch Hikers guide has the first two parameters backwards.
The Dri GemDos spec has the definition of Set backwards.
The St internals book also has the definition of Set backwards.
The St explored book does not document this function at all !!

More Megamax C madness:
  I guess the people over at Megamax C discoved the same mistake in the hitch hikers guide (first two parameters backwards). So what they did was in <osbind.h> they

#define Fdatime(a, b, c) gemdos(0x57, b, a, c)
```

reversed the first two parameters for us. You can imagine my surprise when my code started giving me bombs when compiled with Megamax. I looked everywhere but in Osbind.h, because the last thing you suspect to be wrong are the standard include files. If you look at the osbind.h supplied by megamax, it is written by Atari. So someone at Atari may be the culprit.

BTW Atari (Landon, Neil, Alan) when are you going to release the rest of the missing .h files [signal.h (yes the library does contain signal.o), setjmp.h, dir.h etc) and the rest of the utilities (ranlib, tsort, lorder - they are documented in the Alcyon document that you give out without bothering to even mention why the documented

functions are not provided - a simple we have'nt done it as yet will
put the mind to rest). The developers kit has been out for over a year
now and i feel that now its about time that at least standard
header files are distributed by Atari, if nothing else, to avoid a
zillion different versions of the same files, and the resulting
disaster. So don't just claim V7 library compatibility with the new
release of the kit (seen several message from atari that state this)
DO SOMETHING ABOUT IT. I'll step off now.

The Coco sounds very intriguing, as the 6809 may be the ultimate evolution of
the 8-bit art form... but what's this nonsense about MSDOS machines being
more powerful than a 68000? That seems a gross overstatement at sent, at
least until the 80386 generation of machines comes out. From what I have
heard, a 68000 will blow away an 80286 every time! And of course it is silly
to even speak of an 8088 in the same breath.

In article <1040@ihwpt.UUCP> knudsen@ihwpt.UUCP (mike knudsen) writes:
>Radio Shack marketing has found a nice gap in the market
>and filled it pretty well -- the space between the 8-bit
>home "toys" and the 68K machines (which MS-DOS users would
>call "toys" too).

Actually, they are quite justified in calling them toys. Just as much so as
someone who owns a Pinto is justified in calling both go-carts and
Porsche 944 Turbo's toys (admittedly, 944's usually don't cost less than
Pinto's).

If it's fun, it's a toy. MS-DOS machines are not fun.

> [Stuff about a some vendor selling a CD-rom full of public domain software for $195...] Next, comes the part about suing. They cannot be sued for selling public domain software. They can be sued for selling copyrighted software without permission (big difference). GNU (the 'public domain' UNIX clone) cannot legally be sold for a profit, because it is copyrighted. It can be distributed free of charge (or, I think, with a minimal copying fee - you'll have to pay for the tape/disks you get it on) but not sold. ...

There is no problem with selling copies of GNU, or support services for it, at a profit. What GNU's copyright terms do not allow is trying to restrict further redistribution of any version of GNU that you sell. The vendor has to pass on the same rights to the recipient that s/he him/herself had (including the right to give away copies)--- that is, proprietary versions are not allowed. The only other restriction is that if any GNU-derived software is distributed in binary form (such as in ROMs), it must also be made available in machine readable source code form at nominal cost to anyone asking for it. (Also, the customer must be informed that the Free Software Foundation does not provide any warranty for the software.)

See the GNU Emacs General Public License for details of this. Other parts of the GNU system will be released under very similar terms. I will mail copies of the General Public License on request.

Paul Rubin
Free Software Foundation

P.S. As long as the contents of the CD-rom that that place is selling
is still PD, I don't find it too objectionable. As long as the people
selling the CD-rom do not try to prohibit others from copying it,
possibly also in CD-rom form, the price should fall pretty fast.

I've had a 1040 for a few months, and it gets warm over the power supply, but
the case isn't in danger of melting. I couldn't imagine survival with power
bricks and single-sided drives floating all over my desk.......

I in fact did this a while back for a program, that i luckily have handy here on the system. Here is the relevant function from the program.

--
```
#include <osbind.h>
/* tsr_ptr points to the 8 bit TSR register of the 68901 */

static unsigned char *tsr_ptr = (char *)0x00fffa2d; /* See St internals      */
static long *hz_200 =  (long *)0x000004ba; /* Yes the Hitch Hikers Guide
                              is wrong!! */
/*
 * send a break
 * Modifies Bit 3 in the TSR (reg 23) of the Mfp
 */

sbreak()
{
     register long save_ssp;
     register long time;

     save_ssp = Super(0L);   /* Super Mode */

     /* set bit 3 of the TSR */
     *tsr_ptr |= (unsigned char)8;

     /* wait for 250 ms -- you can adjust the duration
      * 250 ms seems to be almost a universal figure for break
      * duration.
         */
     time = *hz_200 + 50;
```

```
     while(*hz_200 < time)
          /* wait */ ;

     /* reset bit 3 of the tsr */
     *tsr_ptr &= (unsigned char)~8;

     Super(save_ssp);   /* Back to user Mode */
}

I noticed that the ST disk format and the MS-DOS disk format are
similar but different. Are there any programs available which can
(assuming compatible drives size and bit-wise):

a) convert an ST disk to MS-DOS and vice-versa or
b) read and/or write an MS-DOS format disk on the ST

Fine. I guess that leaves me with a 520ST computer and a lot of
non-copy protected software that's not worth copying anyway.
While there are some excellent packages that are not protected,
most of the really useful stuff IS protected.
While boycotting vendors of copy protected software
may well teach THEM a lesson (or put them out of business),
it doesn't leave ME with much useful software.
Besides, it only teaches THEM a lesson if they know that the reason
their software is not selling is because of copy protection.

Did you buy your computer to teach people lessons or to use it?

> The Coco III has 128 to 512K, graphics nearly as good as the ST or Amiga...

Really? 640x400 pixels in 16 colors out of a palette of 4096? Bit blitter? Video coprocessor? Well, then, how about comparisons to the Atari. Lets see, the Atair gives you 640x400 monochrome. Nope, can't do that. 640x200 in 4 colors out of a palette of 512. I think the quoted resolution was 640x192 with 4 colors out of a palette of 64. Not bad, but if they're really going to the added expense of an RGB analog (over RGBI digital) monitor, why settle for just 64 colors (2 bits each of R, G, and B). Also, the 6809, while one of the nicest 8 bitters, is going to be hard pressed speedwise to do graphics at this resolution anywhere near the speed of the Atari, much less the Amiga. Of course, in this price range, you're directly competing with the C128 and (if anyone's actually buying them) the Atari 130. The graphics, is true as stated, are better in some ways than either of these. The Atari supports either 128 or 256 colors (can't recall offhand), but its limited to a display of around 40 characters. The C128 has 16 colors each screen (it can support both the 40 and 80 column screens simultaneously). The 40 column screen has a lower graphic resolution, but supports hardware sprites. The 80 column screen can do 80x25 text, 80x50 text (interlaced), and a 640x200 two color bit-map. Its also possible to exchange a few horizontal lines for a limited color bit-map, and the display can actually be set up for around 82 characters across. The 80 column display has some features (block moves and copies) that free up the processor, but there are other things about it that make it kind of slow for many things too. Overall, it sounds like the CoCo-III has an edge over the C128 in the display department.

> 68K home market by landing salvos on both sides of it.

That's silly. The 68000 machines, any 68000 machine, is much more powerful than currently existing MS-DOS machines. The 6809 is in many ways a more advanced processor than the 8088, and at your 1.7MHz or whatever the CoCo-III is running faster memory cycles than a standard or XT PClone. If Motorola had the forsight to add on-chip banking like in the 8088, the 6809 would have had a good chance of catching on as THE 8/16 bit chip.

> ...possibly with the memory mapping and protection that the
> 68K pc's lack.

Has TRS announced an MMU chip for the CoCo-III? Last I heard, none of the 6809 suppliers (Motorola, Hitachi, etc.) had.

> ... the 68K machines (which MS-DOS users would call "toys" too).

And all UNIX users call MS-DOS a toy. Much of this comes from the knowledge that it truly is, since it runs on computers which (at least until the AT)

couldn't dream of supporting UNIX. Of course, all of the 68000 machines will be able to run UNIX quite nicely, along with OS-9 68K, the version of OS-9 for grownups. Show an MS-DOS user an Amiga running a Lotus clone using four megabytes of RAM for its spreadsheet, while at the same time a database, EMACS, and downloading E-Mail in the background, and he'll quickly change his tune. What's a "memory-resident" utility, anyway. Come on! MS-DOS is just an enhanced CP/M; even the 6809 versions of OS-9 are a more sophisticated and powerful solution to the operating system question.

> Commodore and Atari have tried to narrow this gap, with 128K editions of

> away years ago, but some things defy explanation.

The Apple II was successful for exactly the same reasons that the IBM PC was successful (1) Open Architecture, and (2) the company (Apple or IBM, take your pick) managed to get a reputation for having a powerful "REAL" computer, despite opinions to the contrary. This is called MARKETING. CBM, TRS, and most others haven't quite caught on to the same degree yet.

> Sure, the Coco III could use even more keyboard improvement
> (you STILL need CTRL to get the C-language symbols, but at
> least there's real CTRL key *in the ight place*), 512K tops
> may seem limiting (but 6809 code is more compact than 68K binary,
> I'll bet)

Your're right on the code compactness. 68000 op-codes alone are 16 bits long, though of course, running the same bus speed, they're loaded just as fast as a 6809 instruction (8MHz 68000 == 2MHz 6809 for bus speed comparisons). Of course, if your're doing 32 bit arithmetic or many other things, the more advanced 68000 instruction set may produce a tighter solution (like a block move of any amount of memory in 2 instructions, etc. The 6809, at the very least, will have to stop to switch banks). Much of the size of the code will depend on whether a compiler or an assembler is used and if a compiler, how efficient it is.

> and the RS232 is probably still bit-banger software.

The C64 (and C128 because of it) use the same kind of deal for RS-232.

> But against Commodore 128s and Atari 130XEs, Coco III is heavy
> competition indeed. (If you believe that $220 tag; seems too
> good to be true -- I'd have guessed $400-$600 for a Tandy product).

Maybe reasonable competition for the C128, heavy competition for the Atari 130. The C128 still have a number of advantages. Not the least of which is the 6,000,000+ C64s that have been sold already (they estimate that about 600,000 C128s have been sold, though this estimate isn't that recent). The C128's 8502 at 2.04MHz will do some things faster than the 1.7MHz 6809 in the CoCo-III. The 6809 is a better processor, however, and doing some things, like memory moves, multiplys, etc. it'll be faster despite the slower bus. The C128's disk drive is more expensive, but it stores around 350K of data,

and can read MS-DOS and most CP/M disks. The CoCo, as mentioned here, is internally expandable to 512K, the C128 externally expandable for a total memory of 640K. The CoCo's directly addressable memory will be more useful, for general applications, than the C128's DMA addresses expansion memory. Though much of this usefulness depends on how the CoCo III banks its extra memory. The C128 has a very advanced mechanism for this via the MMU chip, the Atari's method (selecting 1 of 5 banks in one 16K segment) is weaker.

The C128 has one undeniable advantage, and that's the bulk of software available for it. There are over 1500 different titles of Educational software alone available for the C64, probably around 4000 games, lots of productivity packages, etc. Nearly every major consumer oriented software house writes a version of every product they sell for the C64. In C128 mode we already have several professional quality word processors, data base and spreadsheet programs, etc. CP/M, while certainly inferior to OS-9, was supported by most of the major business oriented companies that were around before MS-DOS, and, as such, there's lots of business and public domain stuff around for the C128. The CoCo-III will certainly be able to take advantage of the OS-9 software around, but there's much less of that available, and it may be awhile before OS-9 level 2 comes around to let you use any extra memory.

As for someone looking for power, the ST looks like a good deal. It offers a reasonable amount of hardware power, easily comparable to a MAC. The fact that it has an operating system far inferior to OS-9 will be overlooked by many, and will actually be a moot point as OS-9 68K is released, which will certainly blow away 6809 OS-9.

68K machines are toys? HAHAHAHAHAHAHAHAHAHAHAHAHA
Hmm. I seem to be running three concurrent tasks in separate windows
here; must be I'm using an MS-DOS computer (only "real" computers
can do that, right?) Funny . . . and I thought I was using a toy.
              -Mitsu (mitsu@well.UUCP)
P.S. To those who are still blinded by the Big Three ('I', 'B', and
'M' . . .), I'd like to remark that when R.J. Mical began development
of the Sidecar MS-DOS coprocessor for the Amiga, he thought it would
take him 2-3 months to learn the IBM computer. He was pleasantly
surprised to find it took the span of 1 plane flight to learn all the
basic information he needed to know from a couple books he bought on the
subject. He remarked later: "I didn't know what I was expecting . . .
something really amazing, stupendous; what I found was the IBM PC is
just a better Apple II." Not that the II is a bad computer; but the
68000 dwarfs any 808X series microprocessor (and yes, is just a little
better designed than even the 80286). There is nothing amazing about
this; a 68000 can compute rings around an 8088 (and a 68020 can compute
rings around a VAX.)

Many thanks to all of those who wrote back about my problem getting
the avatek 1200 to dial long distance numbers! John Sangster correctly
identified the problem as me. What was happening was the following.
I would let the avatek pulse dial the number a few times and get back
the no carrier message. I would dial the number myself and get the modem
tone and then decide to listen in the next time the modem called.
What I heard was a warning from the phone company that I had misdialed.
I wasn't aware that pulse dial phones will not dial if one is off the
hook. So the bottom line is that when the modem placed the first few calls
it got a busy signal. I immediately assumed the worse possible scenario
and convinced myself the modem wasn't working. Not so, it works like a
charm and I finally got through to the bbs at 2:00am. Now my only
problem is staying awake so I can get through to these busy systems.
So my avatek works like a charm and based on my experience I reccommend
it heartily.

>I had very bad experiences with AVATEX 1200 modems. Don't buy them...
>We sent them back twice... Finally, to make a long story short,
>our dealer exchanged them for Racal Vadic Maxwell 1200V modems.

Perhaps this is a hasty conclusion. Another newsgroup has had numerous
postings saying US Robotics Courier (2400/1200/300) modems (this posting
will come through one, although at only 1200 baud, by the way) are
     (a) great|far better than average|noise-free|etc. or
     (b) terrible|unreliable|pure junk|noise-prone|etc.
The units that reach the field seem to fall at the extremes of usefulness.

I have had experince with 3 Avatex 1200's, one of which I own. Two
were fine. The third did not work, but it also did not pass its built-
in self-diagnostics. It was returned, and the replacement is fine.

Perhaps yours came from a bad lot. If so, then USR is not the only
company that can often (but not consistently) make a good modem.

As a further comment, there is quite a difference between a vendor like SUN buying components, mostly in the US for assembly here in maybe ~1000 unit/month quantitys, and someone like Atari or CBM buying parts in the Far East for sub-assembly there in ~25000 unit/month quantitys.

I wouldn't want to quibble about the numbers here, the point I want to make is that component pricing is based on quantity, location, quality, time, luck and negotiating prowess. One some parts SUN and Atari might pay nearly the same price, or others there might be a factor of 2-4 difference in cost.

In response to Nelson Ng's request for info about a board that permits Mac software to run on an Atari ST:

Yes, the product, called Mac-Cartridge, does exist, but it is not yet available.

It is a simple, elegant design: Mac ROMs are mounted on the board, which is plugged into the ST cartridge port. It was a great attraction at the last West Coast Computer Faire and many people, including Andy Herzfeld, got to see a few Mac programs (MacWrite, MacPaint, etc.) run on the ST.

Many have speculated that Apple is, understandably, hesitant to let a company sell a board which contain Mac ROMs. The bare board, less ROMs (which are available from a variety of sources) will supposedly be sold for $99.00. At least that is the rumor.

The manufacturer, Data Pacific, Inc., has been promising to ship "next month" for the past few months, but as of my last phone call to them (in early July) they still had no firm shipping date. They may still be working on the legal considerations.

The Mac-Cartridge will *NOT* turn an ST into a Mac clone. In the prototype version (which is impressive) the following incompatabilities were evident: Any Mac-programmed sounds were incompatable, and since Mac disks (400/800 K) are significantly different from ST disks (360/720 K) due to hardware differences, all Mac programs must be serially transferred from Macs to STs to run under Mac-Cartridge. Of course this brings up another set of considerations: Is such a tranfer software piracy? How will this work with copy protected disks?

Since I'm not connected with Data Pacific I don't have the latest info. If you want to contact them:

Data Pacific, Inc.
609 E. Speer Blvd.
Denver, CO 80203
(303) 733-8158

I'm also told that San Leandro Computer Club is a good source of information on this product.

<<<< >>>>

  I have a question that I hope that someone out there can answer.
  Yesterday I was installing a disk drive on my 520ST. My system is:
    - 520ST with TOS in ROM and 1 Meg upgrade
    - Monochrome monitor
    - One single-sided SF354 disk drive (standard set-up)
I selected a disk drive (you have to do this in order to install a new one) and changed the drive label to c, this I thought would default to uppercase C. Well when I installed the drive the label was a lower case c. When I double clicked the icon a window opened up where a disk window should but insted of the usual 'C:\' I got 'Cartridge'. This is unusual in light of the fact that I do not have a physical c drive, or a ram disk installed for c.
  When I tried to copy things into this window it said something like 'This folder unavailable for access' or something like that. When I tried to copy a folder from A: to Cartridge it gave me no error message, but it didn't show up as being copied either.
  To compound this bafflement I saved the Desktop so that the new c (Cartridge) drive would remain on the desktop. When I re-booted the system the icon was gone. I viewed the desktop.inf file and I saw this:

```
     ( one of my normal drives )
  #M 00 00 00 ... A FLOPPY DISK@...          (not too worried about #'s)
     ( the c drive that opened as Cartridge )
  #C 00 00 00 ... c CARTRIDGE@ ...
```

   ^
   |---- This is the difference I found. If I changed this C to an M,
like the other disk drives, the icon would appear on boot-up. However,
when I double-clicked on it it would give the familiar 'Disk not available'
error I get when I try to double-click on my ram disk and have not
installed it yet. I could not copy files or folders to this modified
drive, but when I changed it back to a C in desktop.inf all was as
before and the icon was gone on boot-up.
  Questions:
  1) What is this? An icon for the cartridge port? If I plug something
     in there that the ST can read will it show up in this window?
  2) What does the C mean after the # in the desktop.inf file?
  3) If this is a window for the cartridge port, how do I keep it on
     the desktop?

  I would really be interested if anyone could shed some light on the
subject. I realize this is not really that pressing, but how many
other 'unknown' features are there to this system? Thanks for any
help you may provide.

                  Bob

hi.

Does anyone out there know if the Amiga Genlock unit is compatable
with the Atari ST?

Has anyone out there had one for a while? What do you think?
Can anyone post a operational summary or tell me where I could find
one?

Please reply via E-mail.

Thanx

Available? Yes. Expensive? YES! For a $500 system $300 for an os(only) is
expensive. Languages packaged as 3 for $600 is stiff also. Although $200
a piece is not that bad you can't get them seperately!
TLM is being irrational. If they priced it at 100 dollars with a language
they could sell 1 copy per ST sold. (which would be a better profit than
there sales to 15% of the ST owners.)

Well, the ST _can_ read MS-DOS disks off the shelf, but, because the
tandems in the PC are of an older, less flexible type, it doesn't go
both ways.

A question for the Atari folk ---

I have recently heard rumors that Atari will be making available
a RAM loadable version of GDOS? Is this rumor true? If so: great!
When will it be available? From who(m)? How much? Etc etc etc...

On the same note: I recently started playing around with GEM for
an IBM XT. It *does* have GDOS --- believe me, it's nice. Having
different fonts, device drivers, etc is pretty amazing. (You wouldn't
believe the screen dumps I have been able to do to my printer...)
GDOS actually makes the GEM interface tolerable....

Neil? Whaddya say?

I have hesitated to ask for help with this, but am at my wits end.
My program uses a proportional gadget and I am experiencing some
very wierd behaviour. If one clicks in the body of the gadget, all
works as advertized, however, if one clicks and drags the knob, all hell
breaks loose. The gadget image gets replicated outside of the window
that it belongs in and the system quickly crashes. I'm sure it must be
my fault but am at a total loss to see what is wrong. Any ideas?
The gadget is in a subwindow on top of a backdrop window and I am using
version 1.1.

Fact is, the MacCartridge from David Small and Joel Rosenblum uses the
ROM cartridge port, not the DMA port. The last I heard, they were close
to an understanding with Apple that would give them a way to market the
device. I don't have any details or a time frame, but it sounds like the
thing may actually become a real product.

Bruce,
The ST disk format and the MS-DOS disk format ARE the same.
However, since MS-DOS uses 40 tracks some measures have to be taken,
even the ST recognizes 40 track DS disks among others.
Best would be to use a switchable 40/80 track drive, like TEAC FD55GV.
But then another problem arises: The ST assumes 3 msec steprate.
Since a 40 track drive needs 6 msec from track to track you will get
an error and assume that there is a difference in the allocation tables.
But there isn't. There is a possibility to change the step rate in the
system with a simple system call I remember. If you want to know it,
I can dig it out for you. Finally, I know at least one person using an
5" drive to transfer datas from the PC to the ST and vice-versa.

I assume that you must be disqualifying the 6829 (or was it the 6839)
memory management chip for some reason. This chip provided expanded
memory and protection for multiple processes on the 6809. It's also
cheap (about $5 a piece).

If any of you want this chip, you had better hurry up and call your
Motorola dealer and have them get them. They are being dropped this
year. The figuring is that why should you stifle yourself with an 8-bit
processor and banking memory when for close to the same money you can
go with a 68008, use your 8-bit peripherals, have a 20-bit linear
address space and the 68000 instruction set.

Finally, someone else besides me sees at least a few small warts on the ST.
I still like the machine. But the END to all computers it ain't. Not even
for $1000.

I agree 100% -- the OS9/68K support for the ST is way overpriced,
especially compared to Tandy's pricing on 6809 versions.
The new Coco 3 stuff is a large price *reduction* --
OS9 (Level II) plus BASIC09 for $80, compared to $170 for both
before. Yes, you must pay extra for the SW development tools now,
tho I think for most buyers it makes more sense to bundle in
BASIC09 than Assembler, even tho I have reached the conclusion
that BASIC09 sucks clamshells as a serious programming language
(I use C and assembler now).   --mike k

> 6809 suppliers (Motorola, Hitachi, etc.) had.
Yeah! The custom VLSI chip that Motorola makes for the Coco3 is indeed
a REAL MMU -- it maps any 8 of 64 physical 8K segments into 6809 address
space. This chip also includes the graphics, interrupts, and DRAM control.
Since the new Basic has a "protect" option, the MMU may have Read-Only!

> > The Coco III has 128 to 512K, graphics nearly as good as the ST or Amiga...

> the added expense of an RGB analog (over RGBI digital) monitor, why settle
> for just 64 colors (2 bits each of R, G, and B).

Yes, I REALLY wish the Coco3 had 384-400 vertical lines.
Personally, I rate resolution more important than palette size,
tho you're right, it's almost a waste of analog RGB to skimp on it.

> Of course, in this price range, you're directly competing with the C128 and
> the Atari 130. The graphics, is true as
> stated, are better in some ways than either of these.
Yes, this was the main point of my posting. But I considered 512-640
horizontal pixels to be in the same league with ST and Amiga.

> The C128 ... supports hardware sprites.
A lifelong shortcoming of the Coco has been lack of sprite hardware
for games. It's amazing how well Coco does Donkey Kong, Joust,
and Marble Madness without them.

> The 80 column screen can do 80x25 text, 80x50 text (interlaced),
> and a 640x200 two color bit-map.
I honestly didn't know the C128 could do 640 across -- sorry, and thanks.

> Overall, it sounds like the CoCo-III has an edge
> over the C128 in the display department.
Glad you agree.

> > Tandy has straddled the 68K home market by landing salvos on both sides of it.

> had the forsight to add on-chip banking like in the 8088, the 6809 would
> have had a good chance of catching on as THE 8/16 bit chip.

Of course we know the 68K machines are better in every way than the MSDOS
biz boxes. It's just that the 3-piece suit types who define the "real

world" don't see it that way. Fortunately biz types are finding how useful
color graphics and mouse pointing can be.
I'm glad you appreciate the 6809 so highly. Interesting idea, putting
segment registers in it, tho the opcodes are long enuf already.

> Of course, all of the 68000 machines
> will be able to run UNIX quite nicely, along with OS-9 68K, the version of
> OS-9 for grownups.
That's U**X without MMU or protection, as has been argued to death
already. The Coco3 will do a safer job on OS9 Level II than the
Amiga or ST can on U**X. Of course OS9/68K is better than 6809 versions,
tho many of the improvements could be retrofit into 6809 versions,
given the extra memory now available.

> Your're right on the code compactness. Much of the size of the
> code will depend on whether a compiler or an assembler is used and if a
> compiler, how efficient it is.
Boy is that the truth! 6809 OS9 was written in assembler, much of
68K in C, and it shows in the code size.

~~~~~~~~~~~~~~~~~~\ lineater, \~~~~~~~~~~~~~~~~~~~~~

i just found why my port of microemacs 3.7 was failing, it's in the manual so i can't complain, in megamax c short is 1 byte; int 2 bytes; and long 4 bytes. Now megamax is my first experience with c compilers on a micro, so the question is: is this standard ? i would have expected short and int to be 2 bytes and liked short to be 2 bytes and long and int 4 bytes. any comments ?

Keywords: MAKE UUENCODE C

I have lately received a bunch of mail requesting uuencoded versions of 'make' that i posted last week. Sorry for not replying individually.

I do NOT intend to post a uuencoded version of make to the net because:

- There are too many (compile time) configurable parameters (see rules.c and h.h).

- I am not sure what you would want make for if you do not have a C compiler. I can see the need for make to maintain Oss pascal programs. i have never gotten the Oss linker to link successfully from a command line (it always shows some undefined symbol, so do not ask me to configure up a make with default rules for Oss Pascal, unless you also tell me how to correctly run it from the command line). Modula people don't need it, as the new version has mdesk. Besides i don't know how to run modula ii from a command line.

- People who have C compilers other than Alcyon or Megamax. Don't be LAZY -:). Post the diffs.

Keywords: UNSIGNED CHAR ALCYON C MAKE

I received a number of complaints about compiling 'make' with Alcyon C. All the people are having problems with 'unsigned chars'. All such people have OLD versions of the development kit and Alcyon C. The upgraded version (v 4.14) is available from atari. In the mean while you can go ahead and change unsigned char to char in 'h.h', and it will still work. Some people have complained about <ctype.h>. This file was missing in the developers kit origonally, but was later posted to CompuServe. So i suggest you pick it off from there, or ask atari to send you one.

Keywords: PROGEM GEM 15 16 RCS

Here are the next two parts of Tim Orens Progem series. To effectively use part 16, you will need the new release of the resource construction set - RCS.PRG (version 2.0), that was posted to ataridev on Compuserve. Note that the Megamax (or Tdi Modula) resource construction set blows up, so it will not suffice. The part 16 distribution consists of the following files:

```
     wind16.prf    The article
     apndx12.prf   The associated appendix (gemcl16.c & gemcl16.h)
     gemcl16.rsc.uue UUencoded gemcl16.rsc
     gemcl16.dfn.uue UUencoded gemcl16.dfn (with rcs v2.0 a .def is a .dfn
                              file)
     gemcl16.rsh   The C file for the above resourse.
```

After UnSharing these articles, run the *.uue files through `uudecode' to get the binaries.

X.PART XV Coping with GEMDOS
X.PP
XWhile it's fun playing with windows and object trees,  one of
Xthe  day-to-day realities of working with the ST is its  operating
Xsystem, GEMDOS.  A successful application should insulate the user
Xfrom  the foibles and occasional calamities of the machine's  file
Xsystem.  The GEM environment provides some minimal tools for doing
Xthis,  but a good deal of responsibility still rests with you, the
Xprogrammer.
X.PP
XThis column (#15 in the ST PRO GEM series) tries to  address
Xthe  GEM/DOS integration problem by providing you some stock  code
Xfor common functions, along with a discussion of some of the worst
X"gotchas" lurking for the unwary.  The download for this column is
XGMCL15.C, and it can be found in DL3 of PCS-58.  You should obtain
Xand list this file before proceeding.
X.SH A BIT OF HISTORY.
XThere has been a good deal of  confusion
```

Xin the Atari press and among developers over what GEMDOS is, and Xhow it relates to TOS and CP/M-68K. It's important to clear this Xup, so you can get a true picture of what GEMDOS is intended to Xdo. The best way is to tell the story of GEMDOS' origins, which I Xcan do, because I was there.
X.PP
XAs most developers are aware, GEM was first implemented on Xthe IBM PC. PC GEM performed two functions. The first was a Xwindowed graphics extension to the PC environment. The second was Xa visual shell, the Desktop, which ran on top of the existing Xoperating system, PC-DOS.
X.PP
XWhen work started on moving GEM to the ST, there were two big Xproblems. First, no STs actually existed. Second, there was no Xoperating system on the 68000 with which GEM and the Desktop could Xrun. Unix was too large, and CP/M-68K lacked a number of Xcapabilities, such as hierarchical files, which were needed to Xsupport GEM.
X.PP
XWork on porting the graphics parts of GEM to the 68000 had to Xstart immediately to meet schedules. Therefore, CP/M-68K running Xon Apple Lisa's was used to get this part of the project off the Xground. Naturally, the Alcyon C compiler and other tools which Xwere native to this environment were used.
X.PP
XIn parallel, an effort was begun to write a new operating Xsystem for the 68000, which would ultimately become the ST's file Xsystem. It was designed to be a close clone of PC-DOS, since it Xwould perform the same functions for GEM in the new Xenvironment. At this point, the term TOS was introduced. TOS Xreally meant "the operating system, whatever it may be, that will Xrun on the ST", since not even the specifications, let alone the Xcode, were complete at that time.
X.PP
XThe first engineer to work on "TOS" at Digital Research was XJason Loveman. This name leaked to the press, and in some Xdistorted fashion generated a rumor about "Jason DOS", which was Xstill just the same unfinished project. As "TOS" became more Xsolid, the developer's tools were ported to the new environment Xone by one, and the GEM programming moved with them. CP/M-68K was Xcompletely abandoned, though the old manuals for C and the tools Xlived on and are still found in the Atari developer's kit.
X.PP
XAll of this work had been done on Lisas or Compupro systems Xfitted with 68000 boards. At this point, workable ST prototypes Xbecame available. An implementation of "TOS" for the target Xmachine was begun, even before the basic operating system was Xfully completed.
X.PP
XThe other intent for the new operating system was to be a Xbase for GEM on other 68000 systems as well as the ST. Because of Xthis, Digital Research named it GEMDOS when it was finally Xcomplete, thus providing the final bit of nomenclature. "TOS" as

Xnow found in the ST is in fact a particular implementation of Xgeneric GEMDOS, including the ST specific BIOS.
X.PP
XSo, GEMDOS is a PC-DOS clone, but, not quite. There are Xenough differences to cause problems if they are ignored. X(Remember, it looks like a duck, and quacks like a duck, but it's Xnot a duck.)
X.SH GOING FOR IT.
XAs a first example, consider the routines Xopen_file() and create_file() at the beginning of the download. XThey make use of the GEMDOS calls Fopen() and Fcreate(). You will Xnotice that these names are not the ones specified in the Digital XResearch GEMDOS manual. Developers who have used PC GEM will Xalso observe that they are radically different from the function Xnames in the PC-DOS bindings.
X.PP
XIn fact, all of the GEMDOS function calls on the ST are Xdefined as macros in the file osbind.h, distributed with the Xdeveloper's kit. At compile time they are turned into calls to Xthe assembly language routine gemdos(), part of the osbind.o Xbinary. So, if you find the naming conventions to be particularly Xoffensive for some reason, just edit the appropriate macros in Xosbind.h.
X.PP
XIn DRI's PC-DOS bindings, any error codes were returned in Xthe global variable DOS_ERR. In the GEMDOS bindings, the Xoperation result or an error code is returned as the value of the Xcalling function. In the case of Fopen() and Fcreate(), the Xresult is a valid file handle if it is positive. A negative Xresult is always an error code, indicating that the operation Xfailed.
X.PP
XAn application which encounters a GEMDOS error should display Xan alert, and query for retry or abort. The type of loop Xstructure exemplified by open_file() and create_file() should Xbe usable with most GEMDOS functions which might fail. The AES Xprovides a function, form_error, which implements a set of X"canned" error alerts appropriate to the various possible errors.
X.PP
XHowever, this is where the fun starts. For unknown reasons, Xthe form_error on the ST expects to see PC-DOS, not GEMDOS, error Xcodes as it's input! Therefore you need a routine to translate one Xinto the other. The routine dos_error() in the download provides Xthis function. The GEMDOS errors are in the same sequence as Xthose for PC-DOS, but their numerical order is reversed and Xshifted. Notice also that dos_error() does NOT perform the Xtranslation if the error code is less than -50. These codes have Xno PC-DOS equivalent; computing a bogus translation will cause Xform_error to crash. Instead, they are passed through verbatim, Xresulting in a "generic" alert which gives only the error number.
X.PP
XThe other major task in integrating a GEM application with Xthe file system is selecting file names for input and output.

XAgain, the AES provides some assistance with the fsel_input call,
Xwhich invokes the standard file selector dialog.
X.PP
XThere are several drawbacks to the standard file selector.
XOne is that the "ITEM SELECTOR" title is constant and cannot be
Xchanged by the application. This could cause confusion for
Xthe user, since it may not be clear which of several functions,
Xclosely spaced in the FILE menu, was actually invoked. While it
Xmight be possible to find and "rewire" the AES resource that
Xdefines the file selector, it is unlikely that such an approach
Xwould be portable to a later version of ST GEM.
X.PP
XA viable approach to eliminating confusion is to display a
Xsmall "marquee" box, with a message defining the operation, on the
Xscreen just above the file selector. To do this, you must
Xinitialize the location of the box so that it is outside of the
Xfile selector's bounds, and then draw it just before invoking the
Xfile selector. This way they will appear together. Before
Xreturning to its main event loop, the application should post a
Xredraw message for the "marquee" area. The AES will merge this
Xredraw with the one generated by fsel_input, and the result will
Xbe received by the application's evnt_multi.
X.PP
XAnother problem with the file selector is that it resets your
Xapplication's virtual workstation clip rectangle without warning.
XThere are other AES functions, such as objc_draw, which also do
Xthis, but the file selector can be troublesome because it may be
Xthe only AES call used by some VDI-based ST applications.
X.PP
XThe veteran developer will also notice that the file selector
Xtakes and returns the path and filename as two separate strings,
Xwhile the GEMDOS file functions require a fully pathed file name.
XAlso, the file selector doesn't remember its "home" directory; you
Xare responsible for determining the default directory, and keeping
Xtrack of any changes. The remainder of the download and column is
Xdevoted to set of utilities which should alleviate some of the
X"grunt work" of these chores.
X.PP
XThe top level routine in this collection is get_file(). It
Xis called with two string arguments. The first must point to a
Xfour byte string area containing the desired file name extension
X(three characters plus a null). The second is the default file
Xname.
X.PP
XIf the default file name is non-null, then get_file() invokes
Xparse_fname() to break it into path and name. Parse_fname() also
Xadds the necessary "wild card" file specification to the path,
Xusing the extent name given as input.
X.PP
XIf no default file was supplied, or the default did not
Xcontain a path, the routine get_path() is invoked to find the
Xcurrent default directory and construct a legal path string for
Xit.

X.PP
XThe results of these manipulations are supplied to
Xfsel_input. Notice that the result of the file selector is
Xreturned via its third argument, rather than as a function value.
XIf the result is TRUE, get_file() merges the temporary path and
Xfile string, storing the result via the second input parameter.
XThis result string is suitable for use with Fopen, and may be
Xresubmitted to get_file() when the next operation is invoked by
Xthe user.
X.PP
XParse_fname() is straight-forward C. It looks backward along
Xthe file to find the first character which is part of the path.
XThe tail of the filename is copied off, and its former location is
Xoverlaid with the wild card specification.
X
X Get_path() is a bit more interesting. It makes use of two
XGEMDOS functions, Dgetdrv() and Dgetpath() to obtain the default
Xdisk drive and directory, respectively. Note that Dgetpath() will
Xreturn a null string if the current default is the root, but it
Xputs a back-slash at the beginning of the path otherwise. This
Xforces a check for insertion in the root case, since the file
Xselector wants to see something like "A:*.RSC", rather than
X"A:*.RSC". After making this fix, get_path() concatenates the
Xwild card specification derived from the input extent.
X.PP
XThe last routine in the download is new_ext(). This utility
Xis useful if your application uses more than one associated file
Xat a time. For instance, the Resource Construction Set uses both
Xan RSC and a DEF file, with the same base name. New_ext() takes a
Xfully formed file name, and replaces its old extent with the new
Xone which you supply. This lets you quickly generate both file
Xnames after one call to the file selector. Notice that new_ext()
Xlooks BACKWARD along the name to find the delimiting period, since
Xthis character can also be part of a subdirectory name in the
Xpath.
X.PP
XSo we reach the end of the code and this column. Hopefully
Xboth will keep you profitably occupied for a while. July's column
Xwill return to graphics topics, with a look at writing customized
Xrubber box and drag box routines, and ways to implement your own
X"pop-up" menus. August will bring techniques for displaying
Xprogress indicators, associating dialog and menu entries with
Xkeystrokes, and customizing objc_edit.
X.SH I CAN'T HEAR YOU!
XThe Feedback mailbag has been noticably
Xflat of late. There have been a number of compliments on the
Xcolumn, which are much appreciated, and some suggestions for
Xtopics which fall outside the bounds of this series. The latter
Xhave been passed on to Antic for possible inclusion in their new
XST quarterly, START.
X.PP
XOne recurring problem is finding the downloads. A number of
Xthe earlier columns say they are in PCS-132 (the old SIG*ATARI),

```
Xand  one says PCS-57 (mea culpa).   In fact,  ALL of the downloads
Xare  now  in DL3 of PCS-58 (ATARI16).   Filenames for  first  nine
Xcolumns  are  all in the form GEMCLx.C,  where x is  the  column's
Xdigit.   For reasons unknown to me,  the next two files were named
XGEMC10.C  and  GEMC11.C;  the  latest  two  downloads  are  called
XGMCL13.C and GMCL15.C.   The latter naming pattern should continue
Xinto the future.
X.PP
XUndoubtedly,  one reason for the shortage of questions is the
Xamazing ability to get a quick answer on the Developer's SIG, PCS-
X57.   This  is  a  good  sign  of  a  strong  Atari  community  on
XCompuserve.   However,  the  SIG message style doesn't really lend
Xitself  to lengthy explanation,  so suggestions for longer  topics
Xare always welcome here.
X.PP
XFinally,  I  am now beginning the process of collecting these
Xcolumns and some additional material into a book.  In doing so, it
Xwould  be  helpful to know if you feel that any part of  GEM  has
Xbeen  slighted  in my discussions.   If so,  let  me  know.   Your
Xsuggestions will appear in future columns and finally make their
Xway into the book.

X.PART XVI Interface Potpourri #1
X.PP
XThis issue of ST PRO GEM,  number 16 in the series,  presents
Xcode  implementing  several user  interface  techniques:  progress
Xindicators, rubber boxes, and draggable boxes with mouse sensitive
Xtargets.   The  code  also  includes  some  utility  routines  for
```

Xhandling resources, event calls, and VDI line drawing.
X.PP
XThe downloads for this column are available on DL3 of the XATARI16 SIG: PCS-58. Note the plural - in addition to the usual C Xsources stored in GMCL16.C, the files GMCL16.RSC, GMCL16.DFN, XGMCL16.H, and GMCL16.RSH are a template resource for building Xprogress boxes. GMCL16.RSC is the resource binary, and GMCL16.H Xis its symbol binding file, to be used with GMCL16.C. The RSH Xfile is a C image of the resource - you would need STCREATE to Xregenerate it.
X.PP
XGMCL16.DFN is the binary symbol file for the resource. It is Xin the format used by the NEW ST Resource Construction Set. If Xyou are a developer, you should download this new version from DL7 Xof PCS-57. It fixes a number of bugs, and has a much faster user Xinterface.
X.SH MAKING PROGRESS.
XThe need for feedback in interface designs Xhas been discussed in previous columns. One instance which is Xoften necessary is the so-called progress indicator. A progress Xindicator is used when your application is doing a long operation. XIt shows that the function is continuing satisfactorily, and is Xnot hung in a loop. When possible, it also gives an indication of Xthe fraction of the operation which has been completed. The Xthermometer bars on the Desktop format and copy operations are Xexamples.
X.PP
XThe sample code shows two types of progress indicator. Both Xare built within the structure of a dialog resource. The first Xtype uses a variable line of text to describe each phase of an Xoperation as it occurs. The rewriting of the text provides action Xon the screen; the fact that it is different each time gives Xreassurance that the program is not hung. The second type of Xindicator is the thermometer bar. This is more useful when the Xoperation is uniform, allowing you to estimate the fraction Xcompleted. Let's look at the code.
X.PP
XThe routines beg_prog() and end_prog() are common to the two Xtypes. The code is very similar to the standard dialog handling Xprocedure, but is broken into two parts. Beg_prog() assumes that Xthe progress indicator box is defined by a dialog tree named XPROGRESS. Such a tree is provided in GMCL16.RSC. Beg_prog() Xmakes the usual calls to center and draw the box. The rectangle Xcomputed in the centering operation is stored via a GRECT pointer Xpassed in the parameter. This rectangle compensates for the Xoutline around the box, and must be supplied to end_prog() when Xthe operation is complete.
X.PP
XThe first version of set_prog() in the download implements Xthe changing text progress indicator. It looks in a tree labelled XSTRINGS for the object number which is passed as a parameter. It Xis assumed that this object is a G_STRING. The address of the new Xtext is loaded from the object's ob_spec field. (For those with

Xthe new RCS, it would be easy to alter this routine to use free
Xstrings. Simply replace the first two lines with:
X.sp
X.ce
Xrsrc_gaddr(R_STRING, strno, &saddr);
X.sp
Xand supply parameters which are the names of strings in a FRSTR
Xbox.)
X.PP
XOnce the new text is found, the set_text() utility is called
Xto update the TEDINFO attached to object PLINE in the PROGRESS
Xtree. Set_text() will insert the new text address in te_ptext,
Xand the new text length in te_txtlen. Disp_obj() is then used to
Xredraw only the rectangle belonging to PLINE.
X.PP
XPLINE must be defined as a G_BOXTEXT object with a solid
Xwhite background, and with the CENTERED attribute set. It must
Xextend entirely across the progress box. This guarantees that the
Xprevious text will be covered over, and the new text will be
Xcentered in the box.
X.PP
XThe second version of set_prog() implements the thermometer
Xbar progress indicator. The PROGRESS tree also includes an object
XPROBOX which defines the outline of the thermometer. It is a
XG_BOX object with a solid white background, and a one-outside
Xborder. The object PROBAR is nested inside it, with the left
Xedges matching. PROBAR is also a G_BOX, with a solid red
Xbackground and a one-outside border as well. Set_prog() creates
Xthe thermometer effect by growing and redrawing PROBAR.
X.PP
XSet_prog() requires two parameters. Maxc is an estimate of
Xthe total duration of the operation, in arbitrary units. Value is
Xthe (new) amount completed, in the same units. Set_prog performs
Xtwo operations. First, it computes the fraction value/maxc, and
Xsets PROBAR to that fraction of the width of PROBOX. Second, it
Xcomputes the rectangle which is the difference between the old and
Xnew widths of PROBAR, and redraws only that part of the progress
Xbox. This prevents an annoying flash on the screen when the
Xindicator is updated.
X.PP
XThese two types of progress indicators have been presented in
Xseparate routines for convenience in explanation. You can easily
Xcombine them in a single procedure to create an indicator with
Xboth effects.
X.PP
XThe final progress indicator routine is called esc_prog().
XDuring many lengthy operations is desirable to provide an abort
Xoption to the user. Esc_prog() lets you do this by polling the
Xkeyboard for an escape (ESC) character. A zero timer value is
Xused to guarantee an immediate return if no character is found.
XCharacters other than escape are ignored.
X.PP
XEsc_prog() returns TRUE if an abort is requested, and FALSE

Xif the operation is to continue. In your application, you can Xeither pair calls to set_prog() and esc_prog(), or recode Xset_prog() to automatically make the abort check. In any case, Xyou should add an information line to the progress box, telling Xthe user how the operation may be halted.
X.PP
XOf course, this type of progress indicator is not the only Xoption available on the ST. Other ideas such as changing window Xtitles, or displaying a succession of differing icons are equally Xvalid. Sometimes the nature of your application may suggest an Xalternate metaphor. For instance, the progress of recalculating a Xspreadsheet might be indicated by darkening successive columns in Xa miniature image of the sheet. Occasionally, the computing Xoperation is visual itself, and will not require an explicit Xindicator. An example is redisplaying objects in a 2D or X3D drawing program.
X.SH BOXED IN.
XThe second part of the download implements two Xtypes of user interaction using the mouse. The first creates a X"rubber box" on the screen, that is, a box whose size is Xcontrolled by moving the mouse. This is similar to the AES Xgraf_rubberbox call, but allows the box to move in any direction Xfrom its origin, while the GEM function only allows movement to Xthe lower right.
X.PP
XThe second technique allows the user to drag the outline of a Xbox around the screen using the mouse. Again, this is similar to Xthe AES graf_dragbox call, but this version is augmented with code Xwhich "hotspots" selectable objects when the mouse and object pass Xover them. These routines are another illustration of the usage Xof the evnt_multi function, and its combination with VDI drawing Xto create new interaction techniques.
X.PP
XThe "rubber box" subroutine is called fourway_box(). Its Xparameters are the current VDI handle (NOT a window handle!), and Xtwo GRECT pointers. The first GRECT must have its g_x and g_y Xinitialized with the fixed point of the rubber box. The second XGRECT contains an outer bound box for the stretching action.
X.PP
XFourway_box() begins by setting the VDI drawing mode and Xcolor. The exclusive or, black combination guarantees that Xredrawing a figure twice in the same location will exactly erase Xit. Next, the routine asserts the mouse control flag. This stops Xthe window manager from tracking the mouse, with the effect that Xmenus will not drop down during the operation.
X.PP
XThe fixed coordinates are saved in the variables ox and oy, Xand an initial mouse reading is obtained with graf_mkstate. At Xthis point, the event loop is entered.
X.PP
XAt each iteration, the loop finds the upper left most of the Xfixed vertex and the current mouse position, and updates the Xtracking GRECT accordingly. A call to the utility rc_intersect()

Xis used to restrict the size of the rubber box to the given
Xlimiting rectangle. Note that if you need a lower limit to the
Xsize of the rubber box, it can be achieved by adding another GRECT
Xpointer "lower" to the parameter list, and using the call
X.sp
X.ce
Xrc_union(lower, rubber);
X.sp
XThis works because the union operation selects the larger of two
Xrectangles if they are nested.
X.PP
XRub_wait() will be described in detail below. Its returns
Xare the new mouse position, and an indication of the current mouse
Xbutton state. If the button remains down, the loop continues.
XWhen the button is released, the rubber box terminates, since it
Xis a "spring-loaded" modal operation. Before ending,
Xfourway_box() returns mouse control to the window manager. The
Xreturn from the routine is found in the rubber GRECT, and is the
Xfinal extent of the box.
X.PP
XRub_wait() is a utility used by both box techniques. Its
Xpurpose is to do one step of the box animation, and wait for a
Xmouse movement, or the release of the button. Rub_wait()
Xpreserves the state of the screen.
X.PP
XThe first action is to draw an exclusive or'ed dotted line
Xbox at the given rectangle. Next, rub_wait() calls evnt_multi to
Xwait for the mouse button to come up, or the mouse to move out of
Xa one pixel rectangle. When the event is detected, the same code
Xis used to remove the box. A value of TRUE is returned if the
Xmouse button is still down; the curious logical construction is
Xnecessary since BOTH events could occur at once.
X.PP
XA short examination of the vdi_xbox() code is also useful.
XAfter converting the rectangle to polyline format, the vdi_xline()
Xroutine is called. Vdi_xline draws a dotted line, but does not
Xuse the VDI line style attribute. This is avoided because the VDI
Xhas problems with corner points when drawing styled lines in XOR
Xmode. Instead, a selection is made from a set of user defined
Xline styles, based on the direction of the stroke, and the
Xodd/evenness of the starting horizontal pixel. This assures that
Xthe figure will be exactly erasable.
X.SH HOT STUFF?
XThe drag box routine is more subtle, because care
Xis needed to correctly synchronize the movement of the mouse
Xcursor and the box, and the highlighting of target objects. The
Xparameters vdi_handle and limit are identical to those in
Xfourway_box(). The GRECT pointed to by box contains the width and
Xheight of the movable box when hot_dragbox() is entered. On exit
Xit also contains the last x,y coordinates of the box. The
Xvariable tree is a pointer to the root of a resource tree defining
Xthe hot spots for the drag operation. Only objects tagged
XSELECTABLE are hotspotted. Hot_dragbox() returns the number of

Xsuch an object if the box is "dropped" on it, otherwise a NIL is
Xreturned.
X.PP
XInitialization proceeds as above, until the graf_mkstate
Xcall. Here is the first potential synchronization problem. If
Xthe user moves the mouse very quickly after initiating the drag,
Xit may already be outside the box by the time graf_mkstate samples
Xthe position. The min/max operations given lock the box onto the
Xcursor, no matter where it has strayed. The mouse/box offsets, ox
Xand oy, will remain constant for the rest of the operation.
X.PP
XHover_obj will contain the number of the object which is
Xcurrently highlighted. It is initialized to NIL, indicating no
Xobject is currently marked. Hot_dragbox() now enters a loop with
Xtermination conditions identical to the rubber box.
X.PP
XThe current desired position of the box is computed by
Xsubtracting the box/mouse offset from the current mouse position.
XThe rc_constrain() call ensures that the box will not leave the
Xbounding rectangle. Note that rc_intersect would not work here -
Xit would alter the size of the draggable box, rather than
X"nudging" it back into the bounds.
X.PP
XUpon return from rub_wait(), a number of conditions must be
Xchecked to determine the correct object to highlight, if any.
XFirst, we must make sure that the mouse is actually within the
Xlegal bounds. If not, there may be an ambiguous selection, with
Xthe mouse over one object and the box over another. We choose to
Xdo nothing in this case, and set hover_obj to NIL. If the mouse
Xis in bounds, objc_find looks for a target object. If one exists,
Xit must be SELECTABLE, or it is forced to NIL.
X.PP
X Next the new object, stored in ret_obj, is compared to the
Xold highlighted object, in hover_obj. If they are different, a
Xswitch must be made. Since either could be NIL, a check is
Xnecessary before calling obj_toggle to invert/reinvert the screen
Ximage of the object. When the loop is complete, the final
Xhover_obj is returned to normal state before its number is
Xreturned.
X.PP
XYou may notice that this method of highlighting objects is
Xdifferent from the incremental tree descent and rectangles method
Xpresented in column 13. While not as efficient, the objc_find
Xtechnique is simpler to code and may be adequate for many uses.
XIf your program will make heavy use of the drag box routine, or
Xwill have large trees of target objects, you may wish to
Xintegrate the incremental hotspotting algorithm with
Xhot_dragbox(). This would be simple to do; just use evnt_multi's
Xsecond mouse rectangle for the states associated with the hot-
Xspotter. The single pixel rectangles would have to remain, in
Xorder to maintain the animation effects.
X.SH A FEW CHANGES.
XThe observant may have noticed that the

```
Xpromised  code for popup menus did not make it into  this  column.
XInstead,  it  will  appear in column 18 along with more  "graphics
Xpotpourri"  and  feedback replies.   The intervening  installment,
Xnumber  17,  will  present  and  document the source  code  for  a
Xcomplete   IBM/Atari GEM Resource conversion program.   This  will
Xappear  concurrently with Mark Skapinker's article on  IBM/ST  GEM
Xconversions  in  the second issue of START.   While  this  program
Xwill be of direct use to only a minority of ST developers, it will
Xcontain  utility code useful to all,  as well as demonstrations of
Xdialog handling and the internal structure of resources.
X.PP
XFinally,  you  may also notice that the so-called portability
Xmacros have disappeared from the download.   Indeed, they are gone
Xfor good.   Since the beginning of this column,  the growth of the
XST GEM developer community has outstripped that on the PC.   It no
Xlonger  seems  appropriate  to  inconvenience  ST  developers  and
Xviolate  standard C syntax for the sake of Intel's  design  flaws.
XThose  who still need compatibility with the PC may achieve it  by
Xcompiling under Intel large model,  or by writing "sed" scripts to
Xtranslate   (tree+obj)->ob_spec  and  the  like  to  their   macro
Xequivalents.

Well from all of the voting going on over the last
two weeks, I have 40 yes votes, and no negatives. Some votes state that
the vote is a summation for other people at that site. An interesting aspect
is that about 5 or so votes come from across the atlantic.

The following are the actual votes that I have accumulated over the last
two weeks. I think that we have enough to start the newsgroup
mod.atari16.sources so could someone out there (read spaf@gatech)
create the group for me??? The prime motivation is to prevent the Hack
reposting disaster in net.sources.games.

Hope to read a newgroup message soon for mod.atari16.sources...

==========

From: raybed2!linus!philabs!princeton!pupthy!wrs (William R. Somsky)

I'm in favor of a moderated Atari 520/1040ST source group.
(I may even have some worthwhile contributions once I get a compiler.)

From: raybed2!linus!decvax!trwrb!sansom (Richard Sansom)

Am I in favor of a new moderated ST newsgroup?

Yes [x]
No [ ]

If I answered "Yes", which of the following names do I prefer?

mod.520st.sources [ ]
mod.520st [ ]
mod.st.sources [ ]
mod.st [x]

From: <raybed2!linus!decvax!yale!FISCHER-MICHAEL>

So, its time for a vote, you want a moderated atari 520st source
newsgroup??? Send me mail, I'll sum to the net in a week to two.

Sounds good to me.

From: raybed2!linus!philabs!seismo!c3pe!charles

Yes!
(Even though I don't *have* an ST, just a 'lowly' 800XL (well, all right, two)).

You *might* want to name it mod.atari16.sources, though, to be "compatible"

with the existing net.micro.atari{8,16} dichotomy.

From: raybed2!linus!philabs!seismo!mnetor!utfyzx!harrison

Yes please, and thanks very much for volunteering. The ProGem
stuff that bammi has been occasionaly putting in micro.atari16
has been really helpful, but complete working programs are
not only useful in their own right but indicate how to write
similar programs when the Developer's doc etc. is just too
obscure.

From: <raybed2!linus!ll-xn!seismo!mcvax!ukc!sjl>

This would be nice. Personally I would prefer the binary rather than
the source because,

    (a) I am lazy and don't want to compile programs unnecesarily.
        On an unexpanded 520 + ss drive this can take quite
        some time!

    (b) to avoid the problems of programs I want that use compilers
        or languages I don't have (mainly modula2 and pascal).

But if all else fails, send sources by all means!

From: raybed2!linus!ll-xn!seismo!mcvax!nikhefh!u14 (Daan Josephus Jitta)

I support the idea of a moderated news group devoted to the Atari ST serie.
In the organisation I'm working for, there is a quick growing community of ST
owners. You can regard this single article as subscribed by another 10 happy
ST owners.

BTW: I am looking for the sources of the make-utility posted to
     net.micro.atari16 at the end of april '86. Can you -if you have it-
     email it to me or *perhaps better* post it to net.micro.atari16 or
     mod.computers.st (???) so other people can use it to?

From: Skip Montanaro <raybed2!linus!cca!harvard!rochester!steinmetz!montnaro>

Peter,

I agree that there should be a moderated ATARI ST group. But are 520s and
1040s so different that they should be separate? I don't own either. I'm
just an interested observer.

From: raybed2!linus!ihnp4!hoptoad!curt (Curt Mayer)

i think that the name sucks. how about mod.sources.st or mod.sources.atari16 ?
nevertheless, i vote yes.

From: raybed2!linus!decvax!cwruecmp!bammi (Jwahar R. Bammi)

Sound like a good idea. Please could you post some alternate paths to

you also, and also Csnet/Arpa addresses to your site if you have them.
That will certainly make it easier to get things over to you.

From: applicon!raybed2!linus!ll-xn!lll-crg!ptsfa!jmc

Fine with me but the name should be something like mod.sources.atari16
(or some such --- whatever keeps the name from being obsolete for new
models is ok).

From: <raybed2!linus!cca!caip!watmath!looking!david>

I vote an enthusiastic YES !

From: applicon!raybed2!linus!philabs!seismo!rochester!rocksanne!sunybcs!mesches
(Scott Mesches)

I'm all for it, but I don't have a compiler 8-(
what are the chances of a mod.binary.atari520

From: applicon!raybed2!linus!philabs!seismo!rochester!rocksanne!sunybcs!leo (Leo
Wilson)

Heck, yeah, GO FOR IT!

From: George Walker <raybed2!linus!decvax!tektronix!tekig4.TEK.COM!georgew>

Yes, I'd like to see a moderated group. I suggest mod.st, with a
subdirectory for sources. It would be nice to have someone we could
mail to to coordinate things like putting together a list of where the
users groups are, etc., since Neil@Atari doesn't have time.

From: Andrew Smith <applicon!raybed2!linus!philabs!seismo!mcvax!kcl-cs!andrew>

My vote is YES to mod.sources.atari520ST or whatever !

From: Alun Jenkins <applicon!raybed2!linus!philabs!seismo!mcvax!kcl-cs!agjenkin>

One yes vote from me !

From: <raybed2!linus!ll-xn!seismo!mcvax!kbsc!yorick>

I vote YES!!

From: Guy Sirton <raybed2!linus!ll-xn!WEIZMANN!cmcl2!MLSIRTON>

Hi!

Sounds great!
How about mod.520st.binaries?

From: raybed2!linus!ll-xn!cmcl2!TPC862@ESTEC.BITNET

Yes, you have my vote. Only one concern.

I am on BITNET and can follow the info-atari16 because there is a
mirror between usenet and arpa. Will there be such a thing for this
newsgroup ? Or will archives be accessible via a mailserver ? We cannot
FTP through gateways from BITNET. Thanks for the info.

From: <raybed2!linus!ll-xn!rochester!kodak!ektools!bruce>

I vote wholeheartedly yes for a moderated newsgroup of this sort.
After all, the amiga guys got one. Shouldn't the name be mod.sources.
{atari16,atari520,atari-st} instead of the system name being in the
middle?

From: applicon!raybed2!linus!ll-xn!lll-crg!ptsfa!jmc

Fine with me but the name should be something like mod.sources.atari16
(or some such --- whatever keeps the name from being obsolete for new
models is ok).

From: topaz.RUTGERS.EDU!appelbau

Yes!!! A 520 sources groups would be great!!

From: applicon!raybed2!linus!cca!topaz!appelbau (Marc Appelbaum)

I don't have an St yet, but I think it is a very good idea, so I vote
YES....

From: Lynn B. Dobbs <applicon!raybed2!linus!ll-xn!s3sun!sdcsvax!marlin.Nosc.ARPA!
noscvax!dobbs>

I really don't care what you call it :-), butr by all means start it.
There are several ST owners at this location and I am sure we would all e
interested.

Thanks

--Lynn

From: applicon!raybed2!linus!ll-xn!seismo!NLM-VAX.arpa!randy (Rand Huntzinger)

Sounds good to me, I vote yes.

From: Heinz Kindlimann <raybed2!linus!philabs!seismo!mcvax!ethz!kindlima>

I really would like to see a news group for atari 520ST sources.
Perhaps it is also possible to run it as a mailing list.
Also a good idea would be an archive that is accessible in an
automatic way (for people who missed a part).

Thank you for volunteering.

From: Andrew Smith <raybed2!linus!ll-xn!seismo!mcvax!kcl-cs!andrew>

I vote YES for this new news group. Would it be possible for you to post
BB board stuff (from Atari etc.). as we in Europe have no chance of receiving
this sort of stuff over here.

I have an Atari 1040ST, and I've been playing with its bit-mapped graphics.
One thing that the Mac does when running MacPaint is let you start a line
by clicking on a point, then flopping the other end around with the mouse until
you anchor it by clicking again. If the display is bit-mapped, what I'd
expect to see is that every time the flopping line leaves a point on the
screen, that point would have to be redrawn or you'd see a whole row of blank
points in every object crossed by the line. Yet this doesn't happen. Surely
the whole screen isn't redrawn every time a line is moved? An alternative
would be to have two planes which are automatically or-ed together to generate
the display, so one could be permanent and one temporary, but the ST certainly
doesn't do this--does Macintosh?

>The gadget is in a subwindow on top of a backdrop window and I am using
>version 1.1.

Proportionals are tricky things to set up right. I didn't use AUTOKNOB
in one I just did on a window that couldn't be sized - I had a feeling
the AUTOKNOB was for windows that get sized, because it changes in that
case. Anyway, I didn't use that, but you must have an Image and a PropInfo
structure filled in properly and their respective addresses assigned in the
GadgetRender and SpecialInfo.

Also, if you use the method I suggested above, you'll need GAGDIMAGE set.

I had the exact same symptoms you report (Images being splattered all over
the place for a while before the machine croaks), so don't feel so bad!

Hope this helps a little.

     Paul.

I'm having problems pickinp up data coming from the joysticks. The
documentation I have says position info should end up in the keyboard buffer,
but I can't find it there... I can only read data from the firing switch.

I can work around this by reading directly from the ACIA, but...?

Is there a good DETAILED doc available somewhere on the ST custom chips and Yamaha music chip ? The developpers package we get here in France is close to being a bad joke (an expensive one, too).

Sorry if this has been discussed on the net already. I'm just joining the list.

Didier Giralt

The technique used is called XOR (eXclusive-OR). What happens is this:
once the first point of the line has been clicked (or "anchored"), then
everytime the mouse moves, a line is drawn from the anchor to the new
pointer position. However, instead of blindly erasing whatever is underneath
the line, the screen's bit image is preserved by XORing the line's bit image
with the screen image. Now, the _next_ time the mouse moves, the line is
again drawn using the XOR mask, thus restoring the background to its previous
state. Once the mouse positions the pointer in its final location and is
clicked, then the line is drawn "permanently". Of course, most programs
also use the "double-buffer" as well, so that any individual action can
be "undone". Anyway, here's an example of how this works:

```
     Screen:       Line:     Screen XOR Line:

     0010000       0000010        0010010
     0100010       0000100        0100110
     0111000       0001000        0110000 <-- note "hole" in this byte
     0000100       0010000        0010100
     0001000       0100000        0101000
     0000000       1000000        1000000

    XOR Screen:        Line:     Original Screen:
```

```
     0010010      0000010        0010000
     0100110      0000100        0100010
     0110000      0001000        0111000
     0010100      0010000        0000100

> I agree 100% -- the OS9/68K support for the ST is way overpriced,
> especially compared to Tandy's pricing on 6809 versions.

OS9 royalties are based on how much money an OEM pays up front.  The more
you pay up front, the less each copy costs you.  Tandy can afford to put
out megabucks for the OS and langauges and then sell them cheaply.  Smaller
companies just don't have the resources to do that (it would probably be a bad
idea even if they could, since I don't think 100,000 people would buy OS9/68K
even at $100 a copy).

I had heard that they were dropped. But I've heard more on the CoCo-III;
they are using a custom glue chip that does the video display and the
memory mapping. The best information says that this chip manages 512K
bytes of memory in 8K segments, compatible with the OS-9 specifications
for memory management (level II).

> The figuring is that why should you stifle yourself with an 8-bit

Why not buy a 68000 (for around $5 a piece), use your 8-bit peripherals,
have a 24-bit linear address space, a 16 bit data bus, and the 68000
instruction set? A good deal, for the price of a discontinued MMU chip.

the hard drive?

3) What is going on between the cartridge-port clock device and the hard disk? (I recall a recent posting from Atari.) Incidentally, will Atari ever put a battery (or other type that will hold time across powerdowns) clock in the ST family? Given that the machine is really good now, this feature would give it a load of class. It is one of the convenience features that every serious computer should have.

Resolution and palette are often used as substitutes for one-another when displaying images, as any MAC or hi-res ST user can tell you.

> Of course we know the 68K machines are better in every way than the MSDOS

Though some places you can't buy anything except a PC. There are actually aftermarket 68000 boards that fit in a PC case and replace the ENTIRE motherboard. That's so engineers, etc., can get the order for a PC through

purchasing, and the 68000 board as simply an "add-on". The suits are wasting too much money with the IBM-only attitude; hopefully that won't last much longer.

The Amiga could easily use either Motorola 68000 family MMU, or a custom MMU, if hardware protection is required. And a 68010 would really help things along.

I recently (well, actually, some time ago) received the binaries for HACK 1.03 fo rthe atari ST on net.sources. My problem is that these files require a program called "uncompress" to make them usable. This particular program is little used at our site and has been consigned to tape and forgotten. Although the sysop HAS promised to find it for me, I may have to wait for over a month to get it.

So, here's the request...

Could some kind person out there send me a uuencoded binary or the source (if possible) of uncompress so I can play HACK? (binaries are of course for a VAX11/780 w/ UNIX). E-mail would be dandy; posting to THIS news group is fine too. Please to NOT post to net.sources, as that is censored at my site, and I won't see it for weeks.

Naturally, if this poses copyright problems (we ARE a licensed UNIX site), please disregard this.

Thanks in advance,

Mark Brinsmead.

Sigh, one last (after 4 weeks) try to get this message out,

I tried to post the message below some time ago but we have been off the
net for one reason or another for about three weeks. If the requested
(or related info on scsi controllers) info has been posted perhaps
someone would be kind enough to email it to me. Thanks muchly!

>
>>A guy I met at a computer store yesterday had a home-built drive consisting of

>more bugs.

>... He showed us I*S Talk as a complete finished product, and
>went on to talk about how FLASH terminal is full of bugs. When it turns out
>that his product is in much worse shape.

First, this posting is contradictory. Flash (the program) and
I*S Talk can't be both worse than each other.

I use Flash (the program) and am quite happy with it. But: I know (and like) the developers. Whenever I have had a problem, they have fixed it. My problems have not been bugs:

1. Flash does not support some of the more obscure features of VT100 (double-sized characters, for example). The initial version did not support scrolling regions because the authors thought this feature was unimportant. To a UNIX user it is not, so they have put it in.
2. Once the scrolling region was added, I had a problem switching to 48 line mode: the scrolling region was not changed. Now it is.
3. It sometimes takes a few clicks of the right button before Flash notices. The authors tell me that this is a GEM problem. They told me to hold the button down longer but I haven't tried this.

I think that there were some other small problems with the initial version, but I never hit them.

The authors regularly sign on to COMPUSERVE, so you could talk to them there. (This is an observation by me, not a commitment from them). On COMPUSERE, there is a bug list & fix file: in atari16 sig, data library 2 (telecom), brouse with keyword "flash".

My ST makes a great terminal for my UNIX machine. I love using JOVE with a 48 line screen. And it works at 9600 Baud (with flow control).

Subject: Re: Stock Program for Micros
From: SAC.HQSAC-ACMI@e.isi.edu

In 'Better Investing', a publication of the National Association of
Investors Corporation (NAIC), there is an ad for a program called
EvalForm 3.0. The Investment Club I belong to uses version 2.0
with a CP/M based machine. Although the program is designed to
support NAIC methods to evaluate a stock it is an excellent tool
for the investor. Data is gathered from either Standards and Poor's,
Value Line or both and entered into the program. The printout provides
buy/sell/hold price ranges, best price to buy, upside/downside, and
several other valuable stats. The report is about two pages long with
very little wasted space.

For more info write to :

    INVESTOR'S SOFTWARE
    BOX N
    BRADENTON BEACH, FL 33510
    (704) 743-2109
    (813) 778-5515

and identify your computer.

For info on the NAIC or how to start your own investment club write to:

    NAIC

Without a doubt, the micro with the most stock market forecasting software is the IBM PC/XT/AT and clones. I don't have specific recommendations on forecasting packages, but there is so much of it that finding it shouldn't be a problem.

The Atari ST will, it is rumored, be able to run most IBM software with an adaptor to be announced soon (or is it already announced?). However, your friend should probably just go buy an AT clone such as the Zenith Data Systems Z248, or the IBM PC/AT itself, or comparable units from AT&T, NEC, ITT, WANG, Leading Edge and many others. The only reasons for using the Atari ST for this purpose would be to save a lot of money and to have a 68000 processor to play with. From the way you posed the question, neither goal seems especially applicable. Buying a straight AT clone would undoubtedly minimize the unforeseen complications in using standard software.

For a color monitor, I would suggest the NEC JC-1401P3A "Multisync" monitor, which has very high resolution and is one of the few that you can use for word processing without feeling bleary-eyed. (The monochrome text display is the sharpest I have seen on a color monitor.) Princeton Graphics is also said to have a very good monitor. The Atari monitor might also be a good choice at a lot lower price. Any of these would justify one of the hi-res graphics cards that are available for the AT clones.

I can't discuss it since I haven't actually used it, but I hear good things about the ISGUR Portfolio System from Batteries Included, for the Atari ST and MS-DOS. It uses the GEM interface and includes an excellent communications

program, IS-Talk. Hope this helps.

I'm afraid this may be a vicious rumor. I checked our local Toys'R'Us
recently. They were selling ST's for $399 alright, JUST ST's, i.e., the
cpu/keyboard. You have to get the monitor and diskdrive separate. However,

the combined price comes out to $959, which is less than the standard $999 (which I paid). Also, they are only selling (at least here in Austin) 520 ST's, single sided drives, color screens, and VERY little software.

On the same subject, there's a software store that started carrying the ST here in Austin, at the standard prices. But during a computer fair here, they had a show special. Instead of the usual $799 for a monochrome system with one single sided disk, they had 'em for $599! What a deal! Buy one of them, then buy a color monitor separate, and for less than the price of a color system, you get a 520 with both monitors. So, if you keep on the lookout, I bet you can find some great deals.

I'm going to buy a computer near the end of this year, and I'd like your recommendations on the Atari ST's. I've been programming for about 8 years and I've been doing systems programming in C for about two years. I want to have:

1. A machine with a good C compiler, possibly running a Unix variant, for doing development work.

2. A terminal emulator, so I can do my mainframe work from home.

3. A game machine - It's been too long since I've had access to good computer games!

Anyone who answers any of my questions would have my sincere appreciation. There are a LOT of questions here, but if you could answer any

that would be great.

- Sean

GENERAL OPINION

What do you think of it? Is it a toy or a serious machine? How does the keyboard feel? Have yours had any problems?

PRICING

What's the lowest price you've seen for a 1040 ST?

MONITORS

I see a lot of ads for "520 ST with color monitor". Does Atari make a "standard" monitor or are dealers pushing the cheapest color monitor they can find? I'm going to be buying a good Sony 27 inch television about the same time I get this computer. Can such a beast work with this computer? If I bought a nice Princeton Graphics, Amdek, Taxan, etc., would it look much better than the one(s) the dealers refer to?

C COMPILERS

What do you think of the C Compilers available? I don't know of any dealers nearby, so I haven't really gotten a personal look at any compilers. I have heard a bit of raving about Megamax C, mostly good. If you've used Megamax, Lattice, or Aztec C, I'd like to hear what your opinion is of the compiler. I will be doing some serious, hard core development work (in other words, I will be paid for it) that may be transferred to large Unix systems. I'd like a compiler that can handle the same code that the portable C compiler can handle, and I'd like one that doesn't make me wait all year (this is supposed to be an 8 Mhz 68000, no excuses for slow compilers). I'm willing to pay good money if it's a good compiler.

UNIX IMPLEMENTATIONS

I've heard that OS9 has been ported to the thing, but the price for the OS and C compiler is about the same as a complete Atari system! Who's going to buy it? Not me! Perhaps you know if the price of the thing is coming down or maybe you've heard of a different Unix port. Please let me know. BTW, I saw an ad in August Byte for a complete SysV port for the IBM AT for about $450. Not a bad price for a real SysV port with pcc, ftn77, text formatters, and manuals.

CD ROMS

Anyone making an interface for these buggers? The idea of having an online encyclopedia or dictionary or other various databases

is very attractive to me. For the things to work, you've got to have DMA, ethernet, or some other very high speed data transfer. This means you've got to have hardware support. Is it there? Is anyone working on this?

* SOAPBOX TIME *

I saw an ad in Byte for a CD of public domain software that contained the equivalent of 400 or so floppy disks. Sounded great till I saw the price: $195. HOLY RIPOFFS, BATMAN! I'm sure that the media costs less than twenty dollars. They invent a fantastic new media for mass storage, one that brings possible vast software libraries to the average person at low cost, and instead of using it to place this software in the hands of users, these people jack up the price way out of proportion to the media cost. This stuff is public domain! Somebody ought to sue their asses for making a profit from it.

* DOWN FROM SOAPBOX *

STAR RAIDERS

It's been at least three years since I last played Star Raiders, probably more. If it were released today it would still be one of the greatest games around. Is anyone planning on porting the thing to the ST series? It would be stupendously awesome with higher-res graphics and sound. I was even thinking of writing a simple version for the Adage 3000!

Thanks for answering any or all of this. I've been involved with computers for a long time. Some of them cost more than I'll ever make in my lifetime. And yet I've never owned one. This is an important decision for me and I appreciate any and all help.

Sean

A few miscellaneous questions:

(1) Does there yet exist for the ST a Scheme, either public domain or
      commercial?

(2) What is the latest version of XLisp for the ST? (My version is 1.4,
      released in January 1985.)

(3) Does anyone know if David Betz, the author of XLisp, has an Arpanet
      address?

(4) Has anyone found an efficient way to make the ST and a Radio Shack
      Model 100 communicate?

(5) Does anyone know when the IBM emulator for the ST will be released?

Thanks,

Wayne McGuire (wayne@oz.ai.mit.edu)

- That's what the BUYER gets for buying "copy protected" software.
Please, let's all get together and refuse to do that! As things are now,
the pirates copy anyway, and legitimate buyers have problems, not only
with things like an old computer model, but simply with using RAM disks
and hard disks. Would you pay for a book that can only be read under UV
light, and that you're not allowed to read on more than one desk?

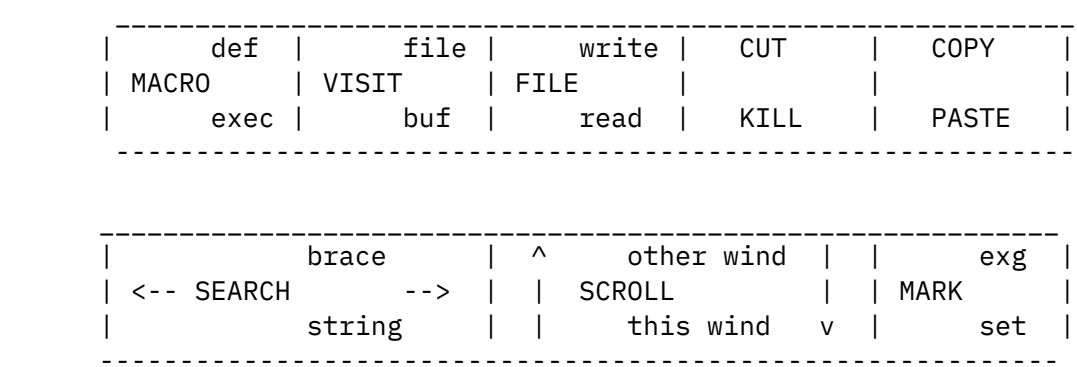
Oops... - the file "flabels" somehow slipped off a disk I copied onto
some peoples' disk as my microEMACS package. So here it is:

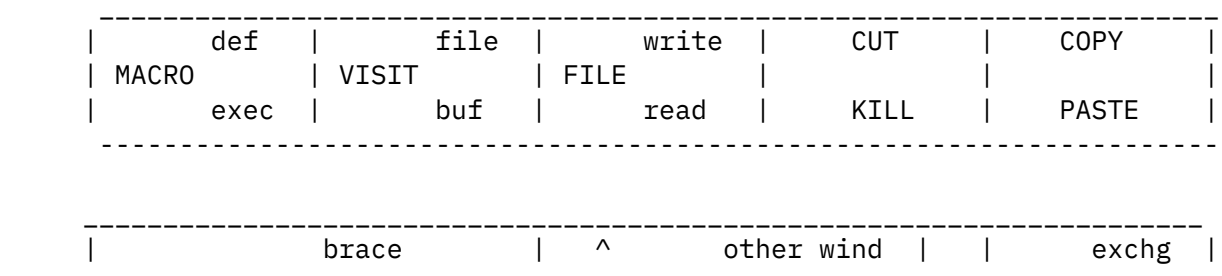
------------- cut -- here --

Print this file to make labels for the F keys.
You can choose between two styles:

For 10 cpi printers:



For 12 cpi printers:



```
    | <---  SEARCH        --->  |   |  SCROLL           |   | MARK        |
    |              string       |   |       this wind   v   |       set   |
    ------------------------------------------------------------------------
```

```
-------------- cut -- here -----------------------------------------

You can still get my enhanced version of microEMACS if you send me an
Atari-ST formatted single-sided 3.5" disk with an appropriate SASE.

The system includes an Atari-made colour monitor which is of very reasonable
quality. It is a little difficult to hook up other monitors, and the Atari one
is plenty good. It was designed to go with the computer, and so the two go
together very well.

The hardware support does exist. Atari has demonstrated the Activenture system at least twice. They have stated that they plan to sell CDROMs... but... not yet. They are looking for the cost (of the players) to come down so that they can market them in quantity. So, whenever players get nice and cheap, you can expect to see Atari selling them. (This is not unreasonable. Atari needs to sell an awful lot of them to be able to make a profit. If they have to sell them at $1200, they won't sell very many.).

>
>   * DOWN FROM SOAPBOX *
It is not necessarily unethical. There was a major discussion on net.micro on the sales of PD software, and the general conclusion was that a company which chooses to make software available should not be denied a profit. NO ONE is going to advertise in BYTE (at at least hundreds of dollars a crack, if not thousands) and compile, copy (onto whatever medium), and mail out software for free. In this case, MEDIA cost may be insignifigant when compared to such things as mastering (making the original CD), the time spent merely putting together the library (how long does it take to copy 400 disks, weeding out anything useless, adding documentation where possible, organizing directories, etc.). Remember here that $195 is pretty cheap. Compare that to the cost of 400 floppy disks. We're talking 50 cents per disk.

Next, comes the part about suing. They cannot be sued for selling public domain software. They can be sued for selling copyrighted software without permission (big difference). GNU (the 'public domain' UNIX clone) cannot legally be sold for a profit, because it is copyrighted. It can be distributed free of charge (or, I think, with a minimal copying fee - you'll have to pay for the tape/disks you get it on) but not sold. Uncopyrighted works, such as many public domain programs can be sold for a profit by anyone who finds someone willing to buy them. It is unlikely that they will be sued for it, given that they have been reasonably careful as to how they have done the job. Is it unethical? To some (yourself included) it is. To others it is not. Please remember that anyone who does not want to pay $195 for the CD of public domain software is not forced to do so. I'm not buying it - but mostly because I have no use for it. If I had a CDROM player, and the right computer, I might find it very worthwhile to purchase the CD at $195.

Atari is working on a version for the ST, and I have heard of some demos
floating about. I hear that it is in fact very stupendously awesome. It
certainly will be one of the greatest games around as soon as it comes out.
When that is, I am not sure (When is it NEIL?!?!?).

My brother has been using the Ansigraf terminal emulation program on
the Atari 520 ST. His comments:

1) The quality of 4014 graphics is very nice at 640x400 mono.
resolution (close to a Graphon 140, for example). I've been using
it with the NCAR plot package on a VAX 11/785 with excellent results.

2) The control of mode switching between vt102/4014 takes a little
time to figure out using the F1 and F2 keys (you can see either or
both of text and graphics screens), but once straight it is very
convenient.

3) VT102 emulation with EDT on VAX is spot on, as far as I've seen.
(except for 132 column mode, which doesn't presently exist... see below)
The Atari keyboard layout is nicely set up for this.

4) Problems with Version 1.0:

i) Only XMODEM file transfer protocol is currently
implemented. The company (i.e., Gyorgy Fekete) said they
are working on ASCII (why not in V1.0???) and Kermit
support.

ii) Only Epson compatible printers are currently supported for
screen prints. I don't currently have such a printer, so
I can't say how well this works.

iii) 132 column mode is not currently available. Eventually you
will be able to pan across to see 132 columns, but because
of limited horizontal resolution on monitor, you won't get
full view on a single screen.

iv) As expected in V1.0, there are a few v. minor bugs (e.g.,
the default setup file should be called DEFLT.SUP, not
DEFAULT.SUP as stated in the manual).

5) In Summary: I've been very happy doing work over a modem line with
the Ansigraf program... as stated above, the tek4014 plots are very
nice, the vt102 emulation works well, and for the price of a 520ST
($600 incl two ss disk drives, mono monitor from 47th St.) and
Ansigraf ($82.45 incl. shipping), you've got a great deal on a
vt100/tek4014 terminal! For Ansigraf, I ordered direct from

I understand that bugs are probably inevitable in large programs but when I read that such and such a commercially sold program is 'full of bugs' I get very annoyed.

Now for the flame:

{utzoo, ihnp4, decvax}!hcr!hugh (Hugh Redelmeier) writes:

>I use Flash (the program) and am quite happy with it. But: I know
>(and like) the developers. Whenever I have had a problem, they have
>fixed it.

>   On COMPUSERE, there is a bug list & fix file: in atari16
>sig, data library 2 (telecom), brouse with keyword "flash".

I'm glad Mr Redelmeier knows (and likes) the developers of Flash. For him a bug fix probably means calling the developers up one evening and then getting a disk with the fixed program the next evening. Other folks, I'm afraid, don't have it so easy.

In addition to having to subscribe to COMPUSERVE, one has to spend ~$20 to get all the bug fixes. That, of course, increases the overall price of the software.

When an end user can find 'lots of bugs' after a short period of time using the product it could only mean that the program wasn't sufficiently beta tested. I won't be suprised that in some cases the process of beta testing goes like:

    Day 1, developer to friend :

        "Hey Joe, would you like to try this program? I'm thinking
         of marketing it."

    Day 2, developer to friend :

        "Hey Joe, I'm shipping the program already; did you have any

problems with the program?"

I'm suprised that the people who purchase these software are so
tolerant. I frequently read reviews like:

    "... there were several bugs but on the whole, I like the XXX..."

Me? I'm still cursing the writers of 'Thunder' because it trashed one
of my files.

This was not meant to be a personal attack on Mr. Redelmeier; I'm just
tired of PAYING to BE a beta tester.

Xref: mnetor net.micro:5746 net.micro.amiga:4084 net.micro.atari16:1483
net.micro.mac:6478

About 9 months ago I posted an article explaining my views on the importance
of a consistent user interface on a single user micro. I still feel that
this is a critical issue, but now it is time to ask if high quality
applications for the Atari ST and Amiga are available. Both machines have
been around for a while and it is reasonable to expect good software.

To attempt to organize the discussion I will suggest some categories, and
provide a summary of what is available for the Mac.

Word Processing

    MacWrite - simple WYSIWYG suitable for many uses
    MS Word - not quite WYSIWYG suitable for most documents

    A whole new generation of word processing software for the Mac is
    about to be released including MS Word 2.0, MacAuthor, MultiWrite, etc.

My impression is that the word processing software available for the Atari ST and Amiga cannot do what MacWrite could on release.

Spreadsheets

    Excel - the best
    Multiplan - pretty good
    Crunch - I do not know it

The only spreadsheet I have heard of on the Atari ST is VIP Planner which did not (when reviewed) use a windowing interface.

Communications

    MacTerminal - OK vt100
    VersaTerm - Excellent vt100, 4014, and others
    Red Ryder - Well thought of, but I do not use it
    many others

    uw - multi-window Unix interface (from John Brunner of LLL)
    Seagate - Appletalk gateway to the internet world (Bill Croft SU)

All sorts of communications software is available and more appears all the time.

Database

    Helix - powerful icon-oriented relational DB
    OMNIS 3 - powerful DB
    OverView - fast DB with some spreadsheet-like features
    FileVision - DB with unique visual interface
    many others

DBase III plus is on the way, and so many others that I lose track.

Development Systems

    Mac C (Consulair) - good C system with many special variants (020 etc.)
    Aztec - as on many systems + symbolic debugger
    Megamax - does the job
    Lightspeed C - Unusually quick integrated environment(editor,make, etc.)
    many others including almost all languages I know and some I don't

More stuff is on the way from Apple and others. Apple are working on reducing development effort using a sophisticated application skeleton (MacApp), Think will have QuickSilver Pascal, others will keep upgrading.

Graphics

MacPaint - the original
FullPaint - what MacPaint would have been with 512K
MacDraw - needs upgrade, but still the best tool I know for diagrams
MacDraft - will be great if the bugs are fixed
many others

Multifunction

Jazz - better than they get credit for
MS Works - we will know when they release it

DeskTop Publishing

PageMaker - the most prominent
ReadySetGo - cheaper
MacPublisher - cheaper

The Mac owns the low end of this market, are there any Atari or Amiga packages?

It remains vital to me that I can transfer data (including graphics) between the applications I use. Another key feature is the relatively uniform support for printed output. By this I mean I can use either a dot matrix printer or a LaserWrite in either portrait or landscape mode from any application.

I have included a copy of my old posting because it still appears relevent. I read too many items about applications that only run in certain environments on the Atari ST and Amiga for my taste. I also do not see any indications that application-independent text-and-graphics cut-and-paste exists except on the Mac.

Please note that I do not want to start a round of "my machine is better than yours" flames. I want reasonable comments on the things which make these machines useful for day-to-day applications. I did not include PC-like systems because until MS Windows (or less likely GEM) becomes accepted they do not offer the same type of environment.

You don't need to buy the developers kit to get schematics for the
520 ST. Howard Sams (Sams Photofacts) sells a very nice set for
about $30.00 I don't think they include a memory map, since they
are mainly for fixing broken STs. Also the schematics I have seen
from the developers kit are incomplete and hard to read.

Summary: Batteries Included on BIX

     Hugh mentioned that the authors of Focus are on Compuserve.
Batteries Included are on BIX (Byte Information Exchange). Of
course, being in Toronto, Hugh and I both have a much cheaper method
of communicating with Batteries Included (Richmond Hill, Ontario).

> the parts really cost.

When I was at Sun, they had pretty aggressive purchasing people.
More to the point is that prices are a function of volume. If Sun
hadn't bought 19-inch non interlaced 1152x900 monitors by the hundreds
in 1984, and gotten the bugs out of them, and ramped up from there, you
wouldn't see these monitors at $1000 now. If next year Atari can bring
out a product that uses them, and sell 20,000 a month, certainly the
price will come down. Similarly if Sun (and others) hadn't been
shipping 68020's for a year, Motorola wouldn't be ramped up to where
they could handle orders for Atari's volume.

When these (currently special) products become standard items, Sun's as
well as Atari's customers will benefit from the coresponding price
reductions.

Low price alone won't bring Atari customers, though. Remember the
first mass market 68000 system (TRS-80 Model 16)? Those clowns sure
didn't know how to make a 68000 hum. From what I hear, Atari is doing
a similar trick with their 68020 project -- hiding it behind a slow
68000 "I/O processor" where it can't get to the outside world quickly.
(I/O speeds in Suns went way up with the 68020, especially screen updates,
disk access, and streaming tape drives.) The Atari ST's I've seen have
been mostly I/O bound and cripped with bad software; a "back-end"
68020 won't fix that.

> could be used in place of the 68000?

This is a red herring. First, a 68010 has the same address space as a
68000. Second, a 68020 just feeds those bits out on pins; if you have
less than 16 megs of stuff to address, you're free to ignore the pins.
Third, if what they are doing is putting the vector number in the high
byte of the interrupt vector address, this is no problem. They will
have to rewrite the interrupt vector code in a minor way for the 68010/20
anyway; in fact, their trick lets them use the same assumptions (e.g. that
multiple interrupt vectors can point to the same routine, but the
routine can tell which interrupt actually happened) in the 68000 as well
as in the later models. I wish I'd thought of it!

It's not hard to write code that figures out which CPU it's on and
copes with the stack frame differences. I wrote that code when I first
got a sample 68010. The system can, at boot time, cause a software
trap and look at the size of the resulting stack frame (6 bytes on
68000, 8 on 68010/20). That test can set a flag that anybody who cares
can check. The test for 68020 is even easier; user programs can do
it. Use an instruction that does scaled indexing. The scaling bits
are ignored on 68000/68010 and used on 68020. (I used "moveq #4,d0"
followed by "jmp pc@(4,d0*2)", which either jumps to pc+8 or pc+12.
You can adjust the constant to suit.) For example, you could stick a
2-instruction test on the front of a multiply routine that, if run on a
68020, would jump to a 32-bit multiply instruction but on the older
models would do it the hard way.

Then don't buy any program until it's been on the market about 6 months.
The primary advantages of being an early customer are:

    *   You get it before everybody else; and
    *   Your opinion about what needs fixing is more likely to be heard,
     since the developers are still actively working on it.

The primary disadvantage is:

    *   It probably doesn't work very well.

But you get to make that tradeoff.

Toys'R'Us is selling the keyboard for $399. The whole setup will cost
you close to list price. Not a very good deal. I have seen a couple
of places offering the SS ST mono setup for under $500 but all offers
ended July 15. Sorry...

....

This is not so. The simplest way to distribute them would be to post the best
programs to net.sources (eunet distribution). Possibly post a list to eunet
and have a vote to decide on what to send first. The rest could go on the next
EUUG tape for one of the EUUG conferences. The most expensive bit is getting
the stuff off USA bulletin boards for us Europeans!

I have been using Micro C-Shell since last November. To answer the
questions quickly; 1) It reads a login.sh file on start-up in which

you can set environment parameters, call other .sh files or programs
and so on. 2) It runs batch files (read shell scripts) just like
executable programs as long as they are in the path. 3) It does not
allow access to the desk accessories (which has become a pain since
I installed the "MacroManager" accessory from Blue Moon Software
-neat, but that's another topic).

Micro C-Shell is a terifically handy product for me. Most commonly,
I run it out of a ram disk (which avoids the only irritant to me, that
it accessess the drive for program reads often if the programs/utilities
don't live in a ram disk). You can configure an environment pretty
much any way you want, with .tos or .ttp programs in a bin directory
or other directory in the user path which is an enivronment variable.
It works so much like csh on 4.2BSD that I have the same aliases and
(most) environment variables the same as I do at work (VAX/4.2) and
do not have to worry about remembering different key sequences or
commands. If you couldn't guess, I like it a *lot*. Also, late word
from the author is that he is releasing the C-Shell with a multi-tasking
operating system and a bunch of new features. I expect to be getting
this, so stay tuned to this channel for a review.

The first issue of STart magazine (disk version) has a screen dump utility
by Tom Hudson. It will let you install the driver of your choice, so when
you hit <ALT> <HELP> it will work with xyz printer. Also, it has a feature
of letting you print vertical or horizontal.

[]

I got this on the STarter kit from John Franco, and I think it is so great
(and short) that I have to post it! It is a RAMdisk program, written by
John Harris, and done right at last! It is NOT a desk accessory. It has
no graphics. It is just an autobooting RAMdisk that will survive system
resets!!!

(It will also work with programs that have a fixed location in low memory,
e.g. Forth systems and applications written in Forth, since it installs in
high memory, as opposed to standard programs and most other RAMdisks.)

First, the doc file by John Harris:

This program gives you a ramdisk between 64K and 768K, and will stay in
memory through screen resolution changes, and even system reset! The
ramdisk code and data is placed at the top of memory, and the screen is
moved down below it. The top of memory pointers are set below the ramdisk
driver, which should keep it safe from everything short of powering down.

The ramdisk install is actually a 2 step process. The 1st time the program is run, it will adjust memory pointers and set-up the ramdisk driver. It then exits through the system reset vector so that TOS can adjust to the new memory size. The 2nd time through, the driver will be installed and ready to use. The easiest way to accomplish this, is simply put the ramdisk.prg into an AUTO folder. That way both passes are automatically performed, in other words, it will auto-boot with no user interaction. The ramdisk installs as drive D, and if you save the desktop after you install drive D, then the boot process will be completely automatic. The ramdisk size defaults to 192K, but can be changed by holding down key combinations of the Right and Left Shift, Control, and Alternate keys.

Configurations are as follows:

R. Shift	64K
L. Shift	128K
R. & L. Shifts	192K
Cntl	256K
Cntl & R. Shift	320K
Cntl & L. Shift	384K
Cntl & R. & L. Shifts	448K
Alt	512K
Alt & R. Shift	576K
Alt & L. Shift	640K
Alt & R. & L. Shifts	704K
Alt & Cntl	768K

If your disk has many desk accessories on it, you should be careful to load a small enough ramdisk so that 128K will be left at the end of the boot.

If the system does crash, put a disk with the ramdisk program in the AUTO folder in drive A, and push the system reset button.

Enjoy! John Harris

Next, a hex dump of this little gem (all 640 bytes of it!)
(you can convert this to a binary file (call it rd192.prg) by using the "htb" program I posted a while ago):

I think my modem is working, but then again...
The avatek works wonderfully for local numbers when using the auto-dialer
in the pulse mode. But when I try to dial long-distance numbers the
telephone company says I've misdialed. Now I've checked this by hand and
its the right number so the modem (or me) is screwing up somehow. I
wonder if any one else has had a similar experience or if I should take it
it for a tune-up. Here's what I do and the resulting problem:
>ATDP17164582638   ; command to dial modem
The modem clicks a lot here and I run to pick up another line to here what's
going on.
Operator: Check the number or call Ma Bell.
The example in the avatek manual shows a long distance number being dialed
without the number 1 preceding the area code. Surely this can't be
right. I'll try this and also try a few other local numbers to see
if the modem has any other problems. Any ideas?

>   notices. The authors tell me that this is a GEM problem.

     Degas version 1.00 had the same problem. But it was fixed in
the later version's (1.10 on or 1.12 on, I believe...). So, it can't
really be a GEM bug, and if it is, it must be something they can get
around. They are just being lazy. The latest version's of DEGAS reply
instantly to the user's clicking on the mouse.

Rick
(FLASH%UMASS.BITNET)

BTW, anybody out there updaded the ST to 4 meg's yet? I heard it is done
easily, I would do it myself now, but I am put back by the deadly
cost of $70 per chip. Let's just hope it goes down soon!
$70 per chip makes the expansion cost more than twice to three times
the price of the ST itself! yipes!

I've tried ST-TERM, FLASH, and AnsiGraf so far and wound up buying
AnsiGraf. My local dealer is great about letting me try software packages
before buying them and loaned me his dealer copy of Flash for several days.
The big difficulty I had with it is that it wouldn't support my local editor
(Ked on a pdp11/73). It also did not work at 9600 baud even though the serial
line was supporting XON/XOFF. It didn't let me do line breaks (inserting a cr)
in emacs on our PRIME. Yeck. I don't know what version this was as it was
a dealer demo and perhaps this sort of stuff has been fixed on later releases.
Flash worked fine when I tried calling a few bbs. AnsiGraf worked perfectly
with both Ked and emacs and also works at 19.2 k baud! I prefer white letters
on a black background and the documentation with AnsiGraf is on beautiful
glossyy
paper and spiral bound. It also does tektronix 4014 graphics viewable at
the same time as the vt102 display. I think Flash is great for bbs'ing but
for use on my computers in the lab it wasn't that useful. As I said in another
letter, I haven't run into any problems in the last 6 days with AnsiGraf and it
took me 2 hours to reject Flash and 2 minutes to reject ST-TERM. I would
love to see a version with tek4105 capabilities but I'm prepared to wait.
But not too long I hope.

Look in your Desk menu for Install printer. (If it's not there, check
the TOS disk for the ".acc" extenders and when you determine which one
is the printer accessory, add it to your boot up disk). Then all you
need to do is click on the Install printer option, and check out the
Pixels/Line option. Try either one and see which works better with
your printer. That should be all there is to it.

X
X    A full featured Public Domain Make for the Atari Sts. Adapted
Xfrom origonal posting by Neil Russell.
X
X    After unsharing the 3 parts of this posting you should end up
Xwith the following files:
X
XSources:
X
X    astat.h       h.h      main.c        rules.c
X    check.c       input.c       make.c        ststuff.c
X    decl.h        macro.c       reader.c  touch.c
X
XAlcyon C compile scripts (you only need these the first time around!):
X    compile.sh
X    link.sh
X    lnk
X
XMegamax C compiler scripts (you only need these the first time around!):
X    mmcomp.sh
X    mmlink.sh
X
XMakefiles for make:
X    makefile  - Alcyon C flavor
X    makefile.mmc - Megamax C flavor
X
XTouch:
X    compiling & linking touch.c will reult in a touch program. touch
X    updates the mod. time of a file to present.
X    Usage: touch file file ......
X
X    #define the symbol MEGAMAX at the top of touch.c is you are
Xgoing to compile touch using the Megamax C compiler.
X
XDocs: (well sort of)
X    readme
X    read.mee
X
X
X    Atari ST specific Information:
X
X    ATARI SPECIAL MACROS:
```

```
X
X    Since the Atari St does not have any standard shell, I have built in
Xthree macros that are useful:
X
X    $(RM)     - removes one or more files, Wild Cards Allowed
X    $(CP)    - copies one file to another. NO directories allowed,
X           will only accept two arguments, both of which
X           must be files. If the destination file exists, it
X              will be overwritten.
X    $(ECHO) - echo's its arguements.
X
X    All atari special commands internally begin with the character '%'
X    and are handled by routines in ststuff.c. It should be trivial to
X    add other Atari Special commands if you so desire. All other
X    commands are executed using the Pexec gemdos command, so complete
X    path names must be used.
X
X    CONTINUATION LINES:
X
X    The line continuation character is '\'. Back slashes may appear in
Xpathname, but NOT at the end of a line, as it will be taken as a continuation
Xbackslash, and not as a part of the pathname. This should not create any big
Xproblem as far as i can see.
X
X
X    DEFAULT RULES:
X
X    See the file RULES.C. I have built in default rules for '.c.o'
Xfor both Alcyon C and Megamax C. But since both use the same '.o' suffix,
Xonly one may be built into the version of make that you compile. Which
Xversion gets built into make depends on the Pre Processor symbol
X'MEGRULES'. If this symbol is defined (see H.H) then Megamax rules get
Xbuilt in. If it is not, then Alcyon rules get built in. All the rules
Xare based on values of macros defined in RULES.C. These macros may be
Xredefined in a makefile, and when the default rule is expanded by make
Xat runtime, the new redefined values will be used instead. Note that the default
Xrule may not be redefined in a makefile. Make will give an error. The only
Xway to redefine the default rule is to edit RULES.C and recompile and link.
XThe values i have used in RULES.C are relevant for our setup. You will
Xprobably want to edit them for your setup. The default rules in RULES.C are
Xas follows:
X
X    .SUFFIXES: .prg .68k .o .bin .s .c .pas
X
X    Alcyon C defult rules (if MEGRULES is not defined):
X    /* Alcyon C and AS68 rules */
X
X    /* Path to the Alcyon C executables */
X    setmacro("CPATH","c:\\bin");
X
X    /* C preprocessor     */
X    setmacro("CP68", "cp68.prg");
X    /* C preprocessor flags    */
```

```
X    setmacro("CPFLAGS", "-i c:\\include\\");
X
X    /* Pass 1 of the C compiler */
X    setmacro("C068", "c068.prg");
X    /* Pass 1 flags           */
X    setmacro("C0FLAGS", "-f"); /* change to "" if you want to use IEEE
X                      * floating point and libm instead of libf
X                      * by Default. Otherwise simply redefine
X                      * C0FLAGS in your makefile to get the
X                      * IEEE floating option.
X                      */
X
X    /* Pass 2 of the C compiler */
X    setmacro("C168","c168.prg");
X    /* Pass 2  flags       */
X    /* setmacro("C1FLAGS", ""); */   /* Save ourselves some space */
X
X    /* Assembler           */
X    setmacro("AS","as68.prg");
X    /* Assembler flags     */
X    setmacro("ASFLAGS","-l -u -s c:\\bin\\");
X
X    .c.o:
X         $(CPATH)\$(CP68) $(CPFLAGS) $< $*.i
X         $(CPATH)\$(C068) $*.i $*.1 $*.2 $*.3 $(C0FLAGS)
X         $(RM) $*.i
X         $(CPATH)\$(C168) $*.1 $*.2 $*.s $(C1FLAGS)
X         $(RM) $*.1 $*.2
X         $(CPATH)\$(AS) $(ASFLAGS) $*.s
X         $(RM) $*.s
X
X    .s.o:
X         $(CPATH)\$(AS) $(ASFLAGS) $<
X
X    /* Linker of choice */
X    setmacro("LINKER", "c:\\bin\\link68.prg");
X
X    /* Relmod */
X    setmacro("RELMOD", "c:\\bin\\relmod.prg");
X
X
X     Megamax C default rules (if MEGRULES is defined):
X
X    /* Megamax C Rules default */
X
X    /* Path to the Megamax C executables */
X    setmacro("CPATH","c:\\bin");
X
X    /* C Compiler    */
X    setmacro("MMCC", "mmcc.ttp");
X
X    /* Code Optimizer      */
X    setmacro("MMIMP","mmimp.ttp");
```

```
X
X    .c.o:
X         $(CPATH)\$(MMCC) $<
X         $(CPATH)\$(MMIMP) $*.o
X
X    /* Linker of choice */
X    setmacro("LINKER", "$(CPATH)\\mmlink.ttp");
X
X    I have not defined any default '.pas.bin' rule for Oss Pascal, but
Xthat should be easy to add.
X
X
X    How to Compile Make:
X
X    Edit the file H.H. If you want to use the Megamax C compiler
Xuncomment the line /* #define MEGAMAX */ to define the symbol 'MEGAMAX'. If
Xyou are using the Alcyon C compiler, leave the line commented out. Edit the
Xfile RULES.C and the symbol 'MEGRULES' in H.H for your taste. If you have
Xthe beckmeyer C shell and my version of CC (posted to the net long ago) then
Xyou may use the shell scripts
X    compile.sh and link.sh - for Alcyon C
Xor
X    mmcomp.sh and mmlink.sh - for Megamax C
X
XIf you don't have CC or microCshell, then you will have to use these scripts
Xas guideline.
X
X    Once make.prg is made, you can safely throw away all the shell scripts!!
XIf you intend to use make from the desktop, rename it to make.ttp.
X
X
X    This program is fully in the Public Domain, and you are encouraged
Xto distribute copies of the program. Your comments/criticisms/fixes etc.
Xwill be very much appreciated. I am however  not responsible for any bugs
Xand/or correctness of behavior of the program. No part of this distribution may
Xbe used for commercial gains.
X
X                  Send your comments to:

```

In-Reply-To: <244@inuxj.UUCP> from Ron Wolenty

According to Abacus' "ST Internals", dosound takes a single longword argument which is a pointer to an array of sound commands:

Command byte (hex)	Function
00-0F	Load the sound-chip register 00-0F. Followed by the byte to load.
80	Load temporary register (kept by XBIOS). Followed by the byte to load.

```
81                      Loop. Followed by a sound-chip register number,
                        a step value (signed byte), and a final value
                        (signed byte). Executes as follows:
                             for temporary := temporary to final by step
                                  do register := temporary.

82-FF                   Delay/halt. Followed by a byte giving the number
                        of system timer ticks to pause, 0 to halt sound
                        processing. A system timer tick is usually 20ms.
```

Subject: Heat problems with 1040s?
To: info-atari16@score.stanford.edu
X-Original-To: "info-atari16@score.stanford.edu"

I'm deciding wether to buy a 1040ST or a 520ST. I want the full meg because the cp/m-68k system I'm now using has 2 megs, and many of the programs I'll be porting need LARGE buffers. But some of the local users and one dealer have warned me of heat failures and design flaws in the 1040ST. Are these isolated problems or is this a chronic concern? If it is chronic, how can it be fixed (why didn't they put a fan in that skinny box?).

Heat concerns me, as do power problems because those are the only problems
I had with my first 68K system. The addition of an integrand power box
with fan cured both. Has anyone installed an Atari board in such a box?
Please, hurry your replies as I need to make a decision within a week.

thanks,

Robert Royar

> difference. Also, most of the quality difference comes in color
> graphics, and I don't care about such. I prefer the mono system.
>
>   Of course, what clinched it for me was the MIDI port.

The Amiga is the more competent machine. The Amiga's system software
is at LEAST an order of magnitude more robust than the ST's. On the other
hand, for pure computation the ST is a wee bit faster. However, the extra
money for the Amiga is well spent. So much for religion.

>
> 2) Religious responses from haters. (NOT APPLICABLE)
>

I like the ST, ALOT. Just not as much as the Amiga.

> 3) Availability of good word-processing software.
>

>

Both fall flat on their chips in this area. For WP'ing, if that's your
MAJOR application a PC clone may be worth a look.

> 4) Reliability (hardware, OS & applications)
>

>

Amiga has OS bugs too. The difference between Atari and CBM-Amiga is
CBM-Amiga is activly pursuing fixing the bugs. So far Atari has ROM'd them
and has seem to have said 'BUGS? Too bad..' Hardware. My 520ST is an
early one so I had the loose chips syndrome. That has been rectified by
new chip carriers. My Amiga is a pre-production model. Even so (or maybe
because of this) my Amiga has been rock solid. No failures at all.

> 5) Sources of info
>
>   Atari maintains a buletin board (The base number is (408)745-5308.

> answer questions. I haven't tried ATARI user support yet. There are a
> number of good user's groups. There is an ST specific magazine, and
> START (a quarterly full of software published by ANTIC) as well as
> Antic. Of course there are the ABACUS books, and I suppose other
> sources.

Same goes for the Amiga and then some. Real system documentation that has
CBM-Amiga's blessing is available form $99 to $450 depending on what you
buy, and who you get it from. Doc's are much better (subjective I suppose)
for the Amiga (less contradictions, more examples, etc). Two magazines
Amazing Computing (Hackers), Amiga World ('USER's').

>
> 6) Comparisons with the Amiga, PC, IBM 1401 :-), etc.
>   Well I don't know about the 1401, but my first computer was a
> 1620, and the ST blows it away. :-)
>   As far as the AMIGA/ST comparison; The Amiga does better/faster
> color graphics, but the ST does clearer mono. The Amiga has a better
> sound chip, but the ST does MIDI. The Amiga has fancy custom
> coprocessors, but the ST is more approachable.

True, th ST is more approachable, at first. Then you quickly realize all
the nice services Amiga built in to the OS and all the choices available
to you as to how you want your application to work/look. Then you look at
GEM for the same choices/services and quickly realize just how
'unapproachable' GEM can be.

 >The ATARI hard disk is
> real. There's currently more ATARI software available. In all, the
> Amiga is a better piece of hardware, but not enough better to justify
> the price.

The Amiga is fully expandable. All it takes is $$$$. Hard disks, RAM (up to 8meg), frame grabbers, digitizers(SP?) both sound and video, card cages (although quite large), 68020/68881 boards, etc. Currently the definitly is more Atari software. That should change, but I'm not a fortune teller.

>   As far as PC's are concerned, the only advantage a PC has is a
> huge amount of software. If you buy an AT (or clone) and max it out,
> you can spend 5-6K and have almost as good a machine as 1500$ worth of
> ST. . .

One other PC advantage is the availability of software that uses the 8087 and 80287. important for number crunching application. And of course the huge variety of plug boards for just about any application.

> 7) How fast is sofware becoming available (PD & Purchased)
>   There is a huge amount of PD Software. Much more than when the
> Mac was a year old. Most of it is very good, well written, etc. I
> have both the PD Forth, and XLisp and use both.

I disagree somewhat. Most of the ST PD software seems poor to me and rarly includes the source for it. On the other hand the Amiga programmers seem much more willing to post both binary AND source, thereby allowing you to modify or enhance it to suit your tastes. Maybe AMIGA programmer's are just more experianced in C, I don't know. I do know that I have aquired nearly 15 megabytes of PD source for the Amiga and some of it is VERY good indeed.

>
>   I don't have as much experience with commercial software, although
> it is certainly there. The only thing I have is OSS Personal Pascal,
> which I highly recommend.

I can also recommend MegaMax C although it has it's problems with complex code (bit fields, function pointers, and some other obscure and not so obscure bugs). Further TDI's Modula 2 seems nice, but I haven't had the time to really use it. I must agree OSS PP is very usable indeed.

I too have little in the way of commercial applications for either machine. I just enjoy hackin' 8^)   I do enjoy Ageis Images on the Amiga.

>   I have seen a lot of stuff in the ANTIC catalog, and most of it
> exists. (I. E. I've seen it for sale at my local ATARI dealer.)

Dealers around the Rochester NY area don't seem to have any of this either. Further, in my user's group, I heard complaint's about very slow ANTIC service.

> 8) Compatability of peripherals
>   This is where the ST really seems to loose. It isn't big enough
> (yet) for a big aftermarket in peripherals, so there aren't many second
> sources, except for the hard disks. The expansion kit isn't out yet,

> so there aren't many places to put them anyway, and ATARI seems to have
> gone out of their way to make it hard to substitute monitors, although
> most of this was to make the machine cheaper to build.

Remember the intial cost difference in the Amiga? Expansion support is a
small part of that. The ST's DMA port is still not the same as the Amiga CPU
Bus connector. Close but no cigar.
>
> A) Anything else.
>
I really like both the ST and the Amiga. If I could buy only one I'd go
Amiga but if funding precludes this, the ST is a good substitute.

How we've help a bit.

It's interesting to see how the new Coco III fits into
the personal computer marketing niche, with respect to
Tandy's product line and its competitors.

The Coco III has 128 to 512K, graphics nearly as good as
the ST or Amiga, a serious-business 80x24 screen (WHEW!)
and a price tag ($220) well under the Commodore 128.

Tandy's line now seems to consist of a series of MS-DOS
machines for the adult/business types at the high end,
with the low end still handled by an 8-bit micro,
the Coco's 6809. Some people may be disappointed that
the Coco III is not a 68000 machine, but Tandy may be wise
to stay out of the King Kong -vs- Godzilla war between
Atari ST and Amiga -- maybe neither combatant will live
to inherit the ruins of Tokyo. Tandy has straddled the
68K home market by landing salvos on both sides of it.

Instead, the Coco III offers graphics almost as good as
the 68K boxes, plus the potential for OS9 Level II,
possibly with the memory mapping and protection that the
68K pc's lack. At a price less than half of a bare-bones ST.

Radio Shack marketing has found a nice gap in the market
and filled it pretty well -- the space between the 8-bit
home "toys" and the 68K machines (which MS-DOS users would
call "toys" too).

Commodore and Atari have tried to narrow this gap, with 128K
editions of their home computers, but
in terms of improvements over their 64K predecessors, the Coco III
is a quantum leap compared to the other 128K 8-bitters.
Of course any of these machines should have blown the Apple II
away years ago, but some things defy explanation.

Sure, the Coco III could use even more keyboard improvement
(you STILL need CTRL to get the C-language symbols, but at
least there's real CTRL key *in the ight place*), 512K tops
may seem limiting (but 6809 code is more compact than 68K binary,
I'll bet), and the RS232 is probably still bit-banger software.
But against Commodore 128s and Atari 130XEs, Coco III is heavy
competition indeed. (If you believe that $220 tag; seems too
good to be true -- I'd have guessed $400-$600 for a Tandy product).

Just for the sake of orthogonality, why not make it "mod.sources.atari16"?

One problem at least is obvious: if you are PULSE dialing and you pick up
another phone, all pulses sent while you are listening will be lost.

Pulse dialing works by OPENING THE CIRCUIT briefly for each pulse. If you are
across the line with another phone, this open circuit will be defeated by the
loop current running through the second phone in parallel.

Try letting the poor modem dial the whole number before picking up the phone.
Dial it once and time the pulses, then let it do its thing on a non-shunted
phone line and I bet it will work fine.

Tone dialing usually works fine even with another phone or two across the
line, as the tones still get through.

  I have seen the demo of Star Raiders, and it is *breathtaking*. I
didn't quite realize how damned good the color screen on this beast is
until I saw that. The colors are fabulous, the motion is smooth and
steady, and the whole effect is very impressive. It wouldn't do
anything, but I watched it for minutes. Now if only I could find a
decently priced TV which would accept the Atari RGB color output!

Could anyone tell me how to assert a break on the 1040ST serial line. I assume this is done with some bit pattern in the 68901 control register.

Thanks in advance.

Sun does not pay $1000 for thousand-line 19" monochrome monitors. When we first started shipping them several years ago, the price was in that ballpark (there was only one supplier), but not now.

It also strongly depends on that size of the tube. 19" monitors cost significantly more than 15" monitors with the same number of pixels.

Re: CPU expansion port, AMIGA vs. ST: It looked to me (and to Paul Swanson
who is a pretty sharp ST hardware person, e.g. upgrading and repairing them as
a 520 dealer) ...it looked to me as though the 520ST cartridge port could
probably be expanded to a full CPU bus extension port with a little effort.
A little machining on the case in this area and addition of a connector with
either the additional pins or all pins, and maybe a bunch of bus transceiver
chips, and you would probably be able to do it. If you used the existing
cartridge port as part of the expansion connection, you would want to put a
cartridge socket in the expansion chassis so you could still use cartridge
software.

So hardware hackers need not despair -- they may be able to expand their ST
just as much as one could expand the more expensive AMIGA. However, third
party hardware vendors doubtless won't spring up as readily, since most ST
owners won't have an expansion connector and if they do there is no guarantee
that it will be the same as anybody else's.

Keywords: Transformer?

I have a friend who is thinking of buying the 520 or 1040 to bring to Germany
with him. He was wondering what the machine would need, i.e. in the way of
step-down transformers. If anyone has any experience using an ST bought in
the US in Germany/Europe, I'd like to hear how the machine holds out.

Thanks.

Could anybody send me the source code for Micro-Emacs?

I do already have the binaries, but I have a German ST with a different
keyboard layout, so I need to change things. The documentation
for that editor (if there should be any) would also be valuable to me.

Thank you very much

Hi,
       I just purchased I*S Talk by Batteries Included. Basically, what I can
say is that the product seems like a good one, but version 1.00 should not
have been released to the market, too many bugs. It is so full of bugs, that
one cannot use some of its main advertised features. If one attempts to use
CUT & PASTE you are going to find yourself with a facefull of cherry bombs
and out on the desktop very fast. Also, its FUNCTION key accessory which is
supposed to let you access ALL of GEM without the mouse, just about, only
works one in every 10 tries. The 50,000 spelling dictionary only works on
the buffer or compose window and NOT on entered text, making it useless.
Forcing one to use THUNDER instead. The program will also crash into more
cherry bombs if you add a new entry and don't give it a breather before
pointing at a menu item. It does have some fast text scrolling, but it could
use some inprovement. If you leave he mouse over certain parts of the window,

the mouse will overwrite the text. The documentation is very confusing and frustrating. The built in HELP functions are useless, but cute. It is missing such basic features, that you would not believe. I use a system that provides for me all the linefeeds I need, but it is impossible to turn off linefeeds from the terminal, ARGH! The compose window is cute, but doesn't allow you to enter more than one line at a time. So not very usefull. The buffer is efficient, but it is NO use without CUT&PASTE. The docs are so bad, that after several hours with the docs, I still have not been able to sucessfully use the KEYS and REPLAY functions at all without crashing. I feel I am using an Amiga with all these crashes. Yucko. With all the hip about B.I. products they turn out to be a VERY below quality company with slapped together programs. THUNDER and DEGAS are great, but I*S Talk is something to stay away with a hot poker until they improve it, unless you really NEED a GEM terminal program. It is the BEST GEM program, since the other ones out there (MI-TERM and FLASH) are worse and have even more bugs.

I do not have access to Compuserve so I cannot pass on to B.I. what I think about their product, and I can't call them until my warranty card gets to them, so I would be VERY happy if someone could foward this to them on Compuserve or somewhere similar. (Neil?) I met with the president of that company at a meeting in Boston, where he proceeded to claim that B.I. were the EXPERTS of the industry when it came to GEM, but it turns out they do need to practice for a couple more months on the magical art of GEM programming. He showed us I*S Talk as a complete finished product, and went on to talk about how FLASH terminal is full of bugs. When it turns out that his product is in much worse shape. Heck, more of the pre-release-still-under-developement stuff I see is in much better shape than this. Well, enough flame, I already lost my money...Now I will have to PAY B.I. for a WORKING upgrade of this piece of unfinished code. Sigh.

I would like to know if it is possible to obtain hardware documentation
for the Atari ST computers: i.e. complete schematics, memory map
(Chip select logic) chip/component lists.

These are available for the Commodore Amiga, for around $30, so I was
I was wondering if there is anything comparable for the STs.
Prices? Availability? Anything, Neil?

Thanks for any information.

Subj.: a slight misunderstanding

Sorry Neil,
 i didn't mean that ATARI U.S.A should start duplicating disks or something like that. Most PD software does arrive in Europe after half a year or so, the problem is that it is distributed commercially, one example: 10 SS disks for $70 (the disks tend to be a bit flaky, so you don't get very much for your money). What I would suggest is, that every few months you send a couple of diskettes with the latest PD programs on them to ATARI Germany (or to a user group) and they make them available in some form (which does not mean they actually have to distribute them, just put them on a BBS or so).

                    Simon.

Some stuff:

1) The bug mentioned concerning garbage returned from fread() has been fixed. The fixed version is now being shipped and provided as a FREE revisionary update; send disks and a SASE.

2) I/O redirection does in fact work, with one caveat: the file name MUST follow the angle bracket with no intervening spaces. In other words,

```
blah > blah < blah
```

will NOT work, while

```
blah >blah <blah
```

will work. This will be tended to at some future date.

3) I know that everyone (well, everyone except me) HATES the text editor because the arrow keys don't do "the right thing" (I suppose according to the ANSI arrow key standard :-)). I've heard comments to the effect that the editor is utterly useless because of this "bug". This is not a bug, but rather a design decision which seems to be unpopular. This will be changed in the next major release. Allow me to point out that I still believe that for movement of over a few lines, the mouse is probably faster once you get used to it. I know, I know, the mouse button is sort of wimpy, but your finger gets stronger after a while. Anyway, anyone who knows of other flaws which render the editor a waste of disk space can send me mail. Some old bugs (specifically, problems with search/replace and with the hard disk driver) have been fixed already.

4) We have noticed a prevailing belief that in order to use the floating point system, programs must be linked to the "double.o" code. This is FALSE. The "double.o"

code is only needed for 64-bit precision. If it is not
specified, the linker uses a 32-bit library which is MUCH
faster. In either precision, double values are stored
as 64 bits, but the 32-bit libraries only compute with
(guess how many...) 32 bits. For casual floating point
computations, DON'T link with "double.o". As to the
various problems with floating point, all have been
fixed and are available with the current revision (the
free revisionary update mentioned above). Along with
the fixes are library routines for absolute value.

PLEASE don't beg me for dates. I don't know. Once again, the
current revision is available for no charge. Call for info.

>   This is supposed to set an environment variable to allow for two single
>sided drives. Hack didn't come with this file.

The file should be called HACK.ENV and contains option strings that would
normally be set outside the program, in a Unix environment. The particular
option you want is   HACKDIR=B:
This sets the 'playground' to your second drive. Your A: drive would have
hack.prg, hack.env and record. The B: drive contains all the other files;
help, hh, rumors, etc. The problem won't actually go away; it'll rear its
ugly head at some later date. I guess you'll get to about level 20, with
a winning game, it'll fail on saving the level, and it'll totally blow away
any possibility of recovery :-) :-)

I have been experimenting with the ATARI 520ST in EXTERNAL SYNC mode
and I am looking for some help. This is not well documented. I will
post a summary of E-mail replies (if I get any). Anyone at ATARI listinging???

Here is what I have done:
Set $ff820a to $fd from $fc and drive HSYNC pin 9 and VSYNC pin12
via 470 ohm resisters from an external source. The video information does
NOT seem to follow HSYNC input *exactly* but rather seems drift for about
a byte then re-sync !!!!

Very odd.
See diagram below.

```
VSYNC    ================================
     H  |.
     S   | . <= Video boarder
     Y   |  .
     N  |   . <= drifting away from the horizontal boarder!!!
     C  |. <= after about 8 pixels it instantly reverts to the
     | . <= boarder again !!!
     |  .
     |   . <= slope is a function of drift from NTSC norm.
     |.
     | .
         etc.
```

The camera is NOT running HSYNC *exactly* at the same HSYNC that
the ATARI would if it were providing syncs. Should not this slack
be taken up in the blanking area? Of course I know little about the
chip as it is....What should I do with *BLANK and DE on the GLUE chip
are they converted to inputs also ????

I am making a sampling digitizer that uses the ATARI for
timing with respect to the syncs. Any help would be MOST welcome.

A question for the house:

I am considering purchasing Micro C-Shell from David Beckemeyer Development
Tools in Oakland. Can anyone fill me in on this product a little bit more
than the article in START magazine did? (Has anyone out there even
used it?)

I am interested in knowing things like:
     - does it allow access to .login or .cshrc files or
       their equivalents?
     - does it allow batch files?
     - does it allow access to the desk accessories?

Any other information would be appreciated.

You may as well simply post the responses, since others might be interested
as well?

Thanks in advance....

I think the BBS is a great way to distribute PD software - especially new stuff. But Atari could help ST users greatly by putting the important stuff like text,disk,memory editors etc. on a few disks and including copies of those disks with new STs. Alternatively, Atari could supply dealers with a few disks so new purchasers could copy them. Some ambitious dealers already do this without help from Atari. Atari can simply state that they are not responsible for any problems caused by the PD stuff. Judging from what I read on the net, particularly the notes on the developer's kit, I would guess that few people would hold Atari responsible anyway. The following, I believe, should be included with every ST:

1. Emacs or equivalent
2. Disk monitor (e.g. JOSHUA or Eli's SECED)
3. Memory editor (e.g. JOSHUA)
4. KERMIT and XMODEM (even if not built into an emulator)
5. EZSQUEEZE (Huffman scheme)
6. STPACK/STUNPACK (for transmitting lots of files)
7. XLISP 1.7 (available on the Atari BBS) + docs
8. FORTH(MACS?)
9. PD assembler
10. PD disassembler (one is being written by the president of our STUG)
11. UUENCODE/UUDECODE
12. File comparison utility
13. 410K/820K formatter (I'm asking for trouble now)
14. PICSWITCH6 (picture viewer - most formats handled)

plus a couple more I can't think of off hand.

Stay away from Data Becker. They are not a reputable company.

I wrote a popular assembler for the 6502 which Data Becker sold pirated
copies of. We didn't find out until Abacus start selling it in North
America. It was odd to read my own manual after it had been translated
into German and back to English.

Abacus dropped the product after they found out it was stolen, but I don't
know if I'll ever get anything out of Data Becker. International lawsuits
are quite expensive.

Anyway, a company that would do this sort of thing (even if they didn't
know it was stolen -- they should check their authors to some extent)
doesn't deserve anybody's business in my opinion.

/*..*/

I think that there is quite a bit of demand for the schematics for the Atari ST series. Recently there was a posting inquiring about it, so this is a meetoo posting.

How about it Atari? A book containing all the juicy details for the hardware hack who cannot justify $300 on a scrape-the-bottom budget (for the official developers kit). Neil, you recently mentioned a book slated for December to contain the official documentation. Will this book contain hardware info?

Regards,

anees

I have Micro C-Shell, and am quite pleased with it. The true UN*X hack
will find the shell to be missing a lot of niceties, but for the casual
user like myself, it's more than adequate. The Shell does have a login
file called "login.sh", but nothing like a .cshrc that I've noticed.
Once you're in the shell, you've left the desktop behind though, as far
as I know, you can't access the desk accessories easily.

The shell handles paths, aliases, history, shell variables, and lots of
other goodies. Also included are some utilities like lpr, more, pr, etc...
It's very easy to set up a nice working environment. Beckemeyer, bless his
heart, doesn't use any of that obnoxious copy protection stuff, so you
don't have worry about dropping pizza on the master disk (I almost did that
to my PC/InterC*mm disk once. I wouldn't have bought it if I'd have realized
what a pain that protection scheme would be).

My one major gripe is that the shell won't run from the "auto" directory.
My guess is that it's because the shell feels obligated to give you a
nice full-screen logo, complete with button, before becoming sane again
and giving a prompt. Personally, I would dispense with the desktop altogether
if I could, but I'm forced into it just long enough to double-click on the
shell.

With all the hoopla about the Atari 520ST and company, I would like to start a moderated newsgroup about it, and will serve as moderator. I think the name should be mod.520st.sources, or some other name. I would check out any source since I have a 520, and can prove it works. I am the news SA at applicon, so it
wouldn't be hard to maintain it.

So, its time for a vote, you want a moderated atari 520st source newsgroup??? Send me mail, I'll sum to the net in a week to two.

I recently received this request for an Atari version of emacs along with a reply to a request that I had sent out on the net. Since I do not have this emacs, perhpas someone else can help. Please send mail directly to the original requestor and not me. Thank you.

I've been using Micro C-Shell extensively for the past 6 months and have been
very happy with it. I've just sent away for the multi-tasking version,
MT C-Shell, and am looking forward to using it. Now, for your questions:

     1) Yes, it will read a file 'login' upon startup. This lets you
        setup your aliases, environment variables, etc...

2) Yes, the batch files are basically shell scripts, you have
   foreach, if, and a few others available to you.

3) I don't recall being able to run accessories, you can run gem
   programs though. I just sent in for an updated version, perhaps
   the current version allows this - but I'm not sure.

It comes with a good set of tools, and there is a C-Tools package available
with a bunch more. I'll post a review of MT C-Shell as soon as I get it.

Disclaimer: I have no connection with Bekemeyer Development Tools, I'm only
a happy customer.

I have just completed a mod to my keyboard chip to (supposedly) have it keep
the time after I power down. I had to include two NAND gates to keep the
reset hi. The setup works OK on a friends who has a REV 2.0 6301 chip, but
alas, I had to buy my 520ST when it first came out, and I have a rev 1.0 chip.
The problem is that the time in the chip never increments, it is always
frozen at the same time. What is the difference between the two chips, and is
there anything I can do to get the clock in the chip to work? (It doesn't
work right now!!!!!!!)
Neil, do the old keyboard chips not have a real working clock in them?
I noticed that the new keyboards have a different electronic component layout.
can anyone shed some light, before I have to go out and buy a new keyboard?

I felt good that I bought an ST when it first came out, but now I am wondering

if I shouldn't have waited for the rev B models.

Mike

It was bound to happen: a disk went bad on me and I did not
have a backup. Using MUTIL I could see that the data was there
but the second FAT was damaged. Using the "file attributes"
option of MUTIL I wrote down the starting sector (or cluster)
of each file I wanted to recover. (These cluster and sector are
the two last columns in the directory-entry list of MUTIL).
(I also wrote down the length of the file for later reference.)
Then I used the following program to read each file and save it
on a different drive (a RAMdisk, in my case). This program will
work for MSDOS, by the way. Note that the program reads by clusters,
so you will have some extra junk at the end of the file. If it is a
text file, use a text editor to remove it. Then compare the length
with the original length you wrote down.
Some day I'll try to write a program that will intelligently search
the disk for the required starting-sector information.
(MUTIL did the job but is a PAIN.)

Note: this program assumes a standard disk. If you have a damaged,
"copy protected" disk, well, you get what you deserve for buying
one of those things...

/*

I had very bad experiences with AVATEX 1200 modems. Don't buy them. The
first set of modems that we received would not communicate with some Bell 212
type of modems. We sent them back twice due to the fact that after a couple
of days of use the modems would just die. Finally, to make a long story short,
our dealer exchanged them for Racal Vadic Maxwell 1200V modems.

Call Accolade. Their copy protection does not work with some early 520ST
keyboard controller chips. They have a fix for this. That's what they get
for going beyond the bounds of what we say is OK to use.

I am afraid that you have to go to the developers kit for this. Once we get the information published in book form you should be able to find it locally at places like Waldenbooks, but that will probably not be until the end of the year.

A good idea. Sorry I didn't think of it myself. Disks will be sent ASAP.

Beckemeyer himself recently reported on CompuServe that he is working on
support for desk accessories in a future version (the current is 2.62, I
believe). By the way, the MT/C-Shell is completed and will be shipped
within days, according to his office. Apparently they are finishing up
the documentation. The multitasking capabilities will, among other things,
allow the use of well-behaved TOS programs from a remote system that has
vt52 emulation (no termcaps at first, he says -- sorry). Sounds intriguing.

Well, this works with Megamax. This code changes the interrupt vector
for the MIDI receiver.

VOID jvec();
long sys_vector;

main()
{
     register long *int_ptr;

     int_ptr = (long *) Kbdvbase();       /* get the vector base */
     sys_vector = *int_ptr;          /* get old value to restore */
     *int_ptr = (long) jvec;         /* set new vector */

     /* other code here */

     *int_ptr = sys_vector;          /* restore old vector */

}

PLEASE E-MAIL REPLIES. Thanks.

I have a friend who is interested in the ST, but who has no computer background. Although I do have the background, it is with mainframes, Suns, & PCs. Therefore, I ask: Would anyone care to advise her about the pros & cons of the ST. Specifically:

1) Religious responses from converts
2) " " " haters (if any)
3) Availability of good word-processing software
4) Reliability (hardware, OS, & applications)
5) Sources of info (e.g. user magazines, etc.)
6) Comparisons with the Amiga, PC, IBM 1401 :-) , etc.
7) How fast is software becoming available (PD & Purchased)
8) Compatability of peripherals
9) Good dealers / mail order houses specializing in STs
A) Anything else.

Thanks much,

David M. MacMillan, KB6MPN

Well, it would seem that the keyboard chip is OK in the rev 1.0
I am still foggy on the differences though, since they are not plug in
replacements (which might mean trouble if it should blow). The mod I have done
keeps time perfectly when the power is off, and when the power is disconnected.
The battery backup which has been circulating for some time doesn't work. It
merely freezes the time. More on this mod in another posting, and look on
your local bbs for some files describing it (I'm sure they will float around).
The mod is $15 and all parts are available from Radio Shack. So don't pay $50
if you can solder. This is PERFECTLY SAFE, and in no way does it affect any of
the chips in the ST, except the keyboard chip (and the lines are only
intercepted from the motherboard (probably could be done with a daughter-board)
On thing, you need a small program to take the time from the chip and set the
gemdos time. About 12 lines of assembly, even less in C.

Look for it soon, on a BBS near you.

Mike

The line-eater devours the tripe ration -- More --
The line-eater vomits!

This posting is a small review of the Sams Computerfacts (tm) technical service data book on the Atari 520ST (in response to a previous posting asking about the availability of schematics, et al.). This book is one of many in a series of computer data books, and it includes schematics, waveforms, parts lists, and service checks for the Atari 520ST computer, monochrome monitor, disk drive, and power supplies.

Before going any further, it's time for the caveats: I am not an EE (even worse, I studied theoretical physics in college), and I am not the world's best schematic reader. I find that the schematics given in the "book" are a little more difficult to follow than those in the developer's kit, but they seem adequate for their purpose. If you have a reasonbly good oscilloscope, the Sams schematics are better since they have waveform photos next to the node to be tested. Another advantage of the Sams documentation is the presence of pin reference diagrams for each of the IC package types and a logic diagram for the LS parts (a tri-state buffer and a tri-state latch).

The servic information and troubleshooting tips seem ok for the gross problems, e.g. "my computer doesn't work," or "I'm not getting any sound out of the monitor;" but it wouldn't be much good for subtle problems that one might encounter when making unauthorized memory upgrades. The troubleshooting tips cover both the monochrome and color monitors. The information on the disk drive gives the procudures to trouble shoot and to make adjustments, although many of the adjustments would require an alignment diskette.

The book (actually three pamphlet-style books stapled together in a nice folder) seems to be quite nice overall, but I haven't yet had to try fixing a machine with it. It covers the 520ST with the Rev B board and TOS in RAM. Most of the information should be useful to ROM TOS and to 1040ST owners. The major drawbacks of the book is that it doesn't contain schematics or

adjustments for the color monitor. Minor gripes: the section marked
"Monitor" contains the disk drive info and vice versa, and the price I paid
($39.95) seems a trifle high.

What is a reasonable price for the TOS-in-ROM chip(s)? A friend was told
$75 just for the chips, $100 including installation. This seems a little
steep. Any comments?

My guess is 47th Street Whatever has the lowest prices. Or anybody else who
offers the 520ST monochrome system for $499 or $495.
CompuClub in Framingham, MA is pretty competitive, for example offering the
520 for I believe $499 currently. For a walk-in store, that is pretty good.
Their phone number is (617) 879-5232.

>Does it use a window?

I believe the GEM limit on the number of windows is 8. The GEM desktop limits
the number of open directory windows to 4 so that there are windows availible
for desk accessories (like the control panel).

The local computer shop up hear (Lafayette,IN) has a rumor that Toy'R'Us in Indianapolis is selling ST's (Mono, 520, 1 SS drive) for $399. I've heard NOTHING to confirm this, but a quick call to your local Toy'R'Us couldn't hurt.

     Well, I've only had my 1040ST for three weeks, but I'll give you my first impressions of the machine.

     (First, my background: I work for NASA as an OS Guru, and work with Cray, Amdahl, Vax, Sun and SGI Un*x systems every day. I'm

writing this on a MacUgly (Lisa with MacWorks,) my officemate has an AT, and other people here have Amiga's. I have owned a (currently broken) Heathkit MS-DOS (NOT PC compatible) machine for several years, and was looking for a fast machine to use in music composition/MIDI control when I bought my ST.)

Let me try to answer your questions.

1) Religious responses: I have had my MacUgly for over a year, and still find it difficult to get simple programs working, because the interface keeps getting in the way of writing code. I wrote a fairly complete utility on the ST using OSS Personal Pascal in less than six hours. GEM has some drawbacks over the Mac Interface, especially in renaming and moving files, but it has some advantages, especially the way that folders turn into real subdirectories.

As far as Amiga versus ST is concerned, the Amiga is a somewhat better machine, but the cost difference is greater than the quality difference. Also, most of the quality difference comes in color graphics, and I don't care about such. I prefer the mono system.

Of course, what clinched it for me was the MIDI port.

2) Religious responses from haters. (NOT APPLICABLE)

3) Availability of good word-processing software.

Your choice of word processor is also a religious issue. There's 1-ST word, which is mediocre, and I have micro emacs which is a text editor, not a word processor. There are others, but I haven't tried them.

4) Reliability (hardware, OS & applications)

Well, a month isn't long enough to tell about the hardware, but mine hasn't broken yet. The software is reasonably reliable, GEM doesn't seem to crash and most of the bugs visible to developers are easy to work around. I use OSS Personal Pascal, and it only has a few bugs, and usually performs better than promised.

5) Sources of info

Atari maintains a buletin board (The base number is (408)745-5308. Neil Harris also appears to pay attention to all (CompuServe, Source, Well, UUCP, etc) possible general networks and is reasonable about answer questions. I haven't tried ATARI user support yet. There are a number of good user's groups. There is an ST specific magazine, and START (a quarterly full of software published by ANTIC) as well as Antic. Of course there are the ABACUS books, and I suppose other sources.

6) Comparisons with the Amiga, PC, IBM 1401 :-), etc.

Well I don't know about the 1401, but my first computer was a 1620, and the ST blows it away. :-)

As far as the AMIGA/ST comparison; The Amiga does better/faster color graphics, but the ST does clearer mono. The Amiga has a better sound chip, but the ST does MIDI. The Amiga has fancy custom coprocessors, but the ST is more approachable. The ATARI hard disk is real. There's currently more ATARI software available. In all, the Amiga is a better piece of hardware, but not enough better to justify the price.

As far as PC's are concerned, the only advantage a PC has is a huge amount of software. If you buy an AT (or clone) and max it out, you can spend 5-6K and have almost as good a machine as 1500$ worth of ST. . .

7) How fast is sofware becoming available (PD & Purchased)

There is a huge amount of PD Software. Much more than when the Mac was a year old. Most of it is very good, well written, etc. I have both the PD Forth, and XLisp and use both.

I don't have as much experience with commercial software, although it is certainly there. The only thing I have is OSS Personal Pascal, which I highly recommend.

I have seen a lot of stuff in the ANTIC catalog, and most of it exists. (I. E. I've seen it for sale at my local ATARI dealer.)

8) Compatability of peripherals

This is where the ST really seems to loose. It isn't big enough (yet) for a big aftermarket in peripherals, so there aren't many second sources, except for the hard disks. The expansion kit isn't out yet, so there aren't many places to put them anyway, and ATARI seems to have gone out of their way to make it hard to substitute monitors, although most of this was to make the machine cheaper to build.

9) Good dealers / mail order houses specializing in STs

I don't know about mai order houses, but a local choice for good dealer is San Jose Computer. (where I bought mine) They are a small outfit, so they don't have a lot of hardware variety, but they seem willing to spend a lot of time talking, and they do have most of the software. I can send you their address if you can't find a better choice close to you.

A) Anything else.

If you are going to do your own programming, and you aren't religious about C, try OSS Personal Pascal. It's relitively clean, runs relitively fast, produces good code, and all of that; but the best part is the interface to GEM and the manual the OSS people have

produced.

     It's almost better than the development system, and costs about 1/4 as much.

     I'm trying to decide which C compiler to buy. I already have personal pascal and the ABACUS books, so I don't know that I need the documentation in the developers kit; especially if the book in December is reasonably cheap.

     I do need a full K&R implemenation, since I will be moving some large codes which use most of the language features. I'm also a Unix hack, so a system with CC/Make would be nice. (I would also like a nice GEM interface like OSS Pascal :-)

     As I understand it, the choices are Lattice C at around 150$, MegaMax C at around 200$ and the developers kit at 300$.

     I would be interested in comparisons of the three systems, in particular as to compiler speed, completeness and robustness.

     If you reply directly to me, I will summarize.

Thanks in advance.

Marty

Does any body know how well the SCSI interface from Supra work? Does it supports all the commands/protocols mentioned in the ANSI SCSI standards or just a subset of this?

Also, I'm interested in what kind of software/support do you get with buying the interface. Are programs to initialize the hard drive included? I'd would like to get a reasonably cheap hard drive to go with the Supra interface, does any body know of one?

Thanks in advance,
Tuan Ho (bnrmtv!tho)

In response to Nelson Ng's request for info about a board that permits Mac software to run on an Atari ST:

Yes, the product, called Mac-Cartridge, does exist, but it is not yet available.

It is a simple, elegant design: Mac ROMs are mounted on the board, which is plugged into the ST cartridge port. It was a great attraction at the last West Coast Computer Faire and many people, including Andy Herzfeld, got to see a few Mac programs (MacWrite, MacPaint, etc.) run on the ST.

Many have speculated that Apple is, understandably, hesitant to let a company sell a board which contain Mac ROMs. The bare board, less ROMs (which are available from a variety of sources) will supposedly be sold for $99.00. At least that is the rumor.

The manufacturer, Data Pacific, Inc., has been promising to ship "next month" for the past few months, but as of my last phone call to them (in early July) they still had no firm shipping date. They may still be working on the legal considerations.

The Mac-Cartridge will *NOT* turn an ST into a Mac clone. In the prototype version (which is impressive) the following incompatabilities were evident: Any Mac-programmed sounds were incompatable, and since Mac disks (400/800 K) are significantly different from ST disks (360/720 K) due to hardware differences, all Mac programs must be serially transferred from Macs to STs to run under Mac-Cartridge. Of course this brings up another set of considerations: Is such a tranfer software piracy? How will this work with copy protected disks?

Since I'm not connected with Data Pacific I don't have the latest info. If you want to contact them:

Data Pacific, Inc.
609 E. Speer Blvd.
Denver, CO 80203
(303) 733-8158

I'm also told that San Leandro Computer Club is a good source of information on this product.

I called Toys Ya Us (the middle letter is the Cyrillic Ya, not an R - must be
a Russkie operation) in Framingham, MA ((617) 872-6242) and learned that,
alas, $399 buys you only a cpu/keyboard and a mouse. Certainly not a monitor
and I believe not even a disk drive. Either way, $499 for a full system is
still the best price I have heard confirmed (e.g. CompuClub in Framingham or
47th Street Whatever).

The good news is that Toys Ya Us is back into selling Atari products,
including the 800XL at $69.95 with a considerable quantity left to sell.
If we all express interest and remind them of the $499 package price for
the monochrome system maybe they will match it.

I recently tried using <ALT> <HELP> to print the contents of the screen
to my Panasonic KXP1080 printer. Unfortunately, the print out is
significantly compressed in the vertical direction and approximately
one third is cut off in the horizontal direction. Does anyone out

in netland know if this is normal and if there's anything I can do
about it?

Thanks in advance,
Craig B. Ziemer

The local ATARI dealer here in Reading sells the ROM chips for $15, or
$25 installed. Someone's trying to rip you off.

Pardon if this subject has been beaten to death, but is there somewhere I can FTP to in order to get software for the ST that's already been compiled? I'm collecting PD software for a friend who has no access to the net, and if I can get the executables to my host (and then to my PC) he can call me up and download (now that a friendly netter sent me Kermit and Xmodem). Thanks for any response.

That sure does sound expensive to me! I paid $20 for the chips and installed
them myself. Twenty-five dollars is not too bad for installation, but I have
seen the service offered for $15.

     In response to the question about Micro C Shell:

All the information below comes from a phone-call I made
to Beckemeyer.

#1: Micro C-shell is a Un*x C-Shell clone. Just as you would
expect, it does not do any multi-tasking (in Un*x, the
OS does the multi-tasking).

#2: They have another offering called the MT C-shell (MT =
multi-tasking, most probably). This MT C-shell (bad choice
of name, I think) is a bit of a Un*x clone. The package
comes with an operating system which allows multi-tasking
and sort of clones Un*x like features (a little like
QNX maybe). It comes with (I think) 4 shells. The default
login shell is set up from /etc/passwd, but any shell
can be executed from within the startup shell. The system
allows job-control (fore-grounding and back-grounding)
of tasks, from certain shell(s) to .TOS and .TTP programs.

#3: I believe MTCS also allows a multi-user facility (I suppose
user #2 logs in via the serial port). Again, this user
gets a shell allocated to him from /etc/passwd. (I forgot
to mention, there is a logon procedure for every user).
There is also a superuser facility to go with these other
facilities :-)

#4: There are permission bits for files ala UNIX, so you can
set certain programs out of bounds etc.

#5: There is one shell which can only be run from the console
(guess why :-)) which allows you to run Gem programs as
child processes under it. This shell does not have any
job-control facility (I believe), so once you get into
a Gem program, you are bound to it until you quit (can't
stop the job). I suppose though, that you can still do
multitasking (print spooling in the background for instance
by doing:

```
% lpr myfile &
% gemshell (or whatever)
(execute some gem program here)
```

#6: MTCS supports I/O redirection, true pipes and so on. (stderr
and stdout are distinct I believe)

#7: It comes with a host of programs such as lpr and a list of
others.

#8: MTCS was in Beta test, and should be shipping about now
(again, this is what they told me 2-3 weeks ago).

#9: Oops, forgot, there is a .login ;-)

All of this is from memory (3 weeks old), so please
correct me if anything here is incorrect. I'm not associated
with Beckemeyer and cannot vouch for the accuracy of the
above information because I have not seen it yet. Sounds great
though, so I went and ordered one!

Regards,
anees

Just to defend ATARI. The only way to distribute such programs in Germany would
be by disks. BBS do not exist in Germany except a few which run over a switched
network (DATEX-P). The simple fact is just that one can not buy a modem and hook
it up as we do here in the US. The German Telephon Company won't let you. A modem
needs to be installed and rented from the "Deutsche Bundes Post" and as far as I

remember this is not a cheap solution.

I've talked to three different hosts with my Avatex and have had no
problems at all. In addition, it performs great on my phone line which
is plagued by RFI from a nearby AM broadcast transmitter. I can plainly
hear the radio over the phone, yet I've had no noise hits at all with
the Avatex, which I can't say for at least two other modems I tried
(Anchor Express, Multitech 1200). For $85, you can hardly go wrong. I
say buy it.

Well, let me try again...

The keyboard clock does work, but not with the 6301v1.0 (which is rev. 1). That is the chip of the early 520STs sold (of which I have one). The good news is that the mod works perfectly with the new 520 and 1040 which have the rev 2.0 chip. The keyboard part number that works is C070240-011. If you have one of the older keyboards, I don't think you can use the mod (I tried for over two days to get it to work -- I wish someone would tell me what the difference between the revs is!!!!!!).
I am getting together a little doc to send over the network which could be followed by a layman (not a schematic alone -- hopefully I can draw a board with the character set)
Anyway, if someone at Atari is listening, please tell me what the difference in the two chips are. I have been on Compuserve in the developer's sig, and there are no documents which explain the difference, not even the new hardware manual.
I could contact the company that makes the chip, but that would be a hassle.

Mike

I've had no problems with my Avatek 1200 yet. My local dealer has hd failures on two out of ten units sold, both of which tested bad using the onboard diagnostic. Hopefully working ones stay working. All in all, I'm very happy with mine.

I've also settled on a trminal program. I'm using AnsiGraf from Grafikon and have been very impressed so far. No glaring bugs so far. I haven't tested the file off-loading stuff yet or screen dumping. The great thing about this program is that it supports Tek4014 graphics viewable simultaneously with a text screen running as a vt102. My only problem so far has been setting up my local software to do the screen switching properly. It doesn't appear possible to do this to the terminal program. I'm not complaining. Of the so-called vt100 emulators that I've seen, this one is hte best. All of the nifty screen editors work, and the graphics display looks really sharp on the 520st. Also, I really like terminal emulators that use bright letters on a dark screen. I should mention that I'm using this in monochrome but it is supposed to work in colour too. It cost 79 dollars sug. ret. but appears worth the price. I've tried Flash and ST-term and the GEM interface in AnsiGraf puts both to shame. I'll see if I can find any bugs and post them if I do.

Another reminder: If you send me an (Atari ST single sided formatted 3.5") disk I'll send you the C source and executable form of my enhanced version of microEMACS. Proff is included as a bonus. (To our European friends: send a check instead, if you like, but in US dollars.)

This version of microEMACS is NOT related to the 3.5, 3.6 versions. It makes extensive use of the Atari ST function keys, but also keeps the old-style control-key command invocations. You CAN switch between insert and overstrike modes, and between case-sensitive and case-blind search, but the command interface of microEMACS is modeless and mouseless, which some people love and some hate. Some of the features added: built-in help, search for complementing bracket, reformat paragraph, goto line number, default file or buffer names in some commands, etc.

By the way: my Avatex 1200 modem malfunctioned, but I sent it for repairs under warranty and they sent me a new one instead. It took 3 weeks, mostly for shipping it back and forth.

My 1040STf also sometimes blinks and reboots. This happens only during the
booting phase, usually upon finishing with what's in the 'auto' folder and
before the desktop appears. And only sometimes. Is something wrong with my
hardware? (BTW - is there any way to control the order in which programs
in the auto folder get executed?)

- Moshe.

>will :-)) I think the best that can be said is that in 5 years it
>will probably be possible. Ah well.

This is no swipe at Sun (whose products I use and admire), but Atari
would probably encounter a major marketing disaster if it tried to
bring out a Sun-compatible right now.

Why? Well, first of all, you need a pretty hefty disk (let's say a good
fraction of an Eagle) to store Berkeley UNIX, along with the necessary
goodies to make it useful. Second, installing a Sun is a non-trivial
job (take a look at the installation manual some time): I'm not sure
Atari's market in general is ready for that level of complexity (sure,
lots of UNIX hackers have ST's, but lots of ST owners aren't UNIX hackers).

Somebody could make a killing with a lean, mean, Berkeley UNIX clone which
was aimed at low cost personal computers like the ST. (At the risk of
getting into the interminable Berkeley vs System V argument, I'd just
point out that much of the interesting graphics etc has been done on
Berkeley Unix machines). The result would be a full-featured, multi-tasking
(and even multi-user, to support bulletin boards) operating system which
didn't require a networked file server.

Maybe OS-9 is the answer; since I've never used it (though I did once read
some of the manuals), I couldn't answer the question.

In any case, without a resolution of the system question, I think Atari
would be foolish to announce a box which required considerable support
and was only of interest to techies. I wouldn't be surprised to hear that
the TT's arrival awaits only two things: lower-cost 68020's, and some good
application/system software to make people want it.

>Does anyone out there know what is included in the TDI Modula-2
>developer's package beyond what is included in the basic language
>package? Come to think of it, what's included with the basic
>language?

The basic package includes an editor (which many people including me
don't like very much, but does have a very nice "find next compilation
error" command), compiler, linker, library, Modula-2 desktop, and
Modula-2 options desk accessory (the latter lets you set search paths
among other things). The library includes GEM/VDI interface.

The developer's version adds a number of disassemblers, a simple
post-mortem debugger, source file cross-referencer, a "high-level"
GEM package, source code for a ramdisk and printer spooler in M2,
and Megamax's outstanding resource editor. The latter alone, if
you do any GEM programming, is worth the developer's price.

The system overall is pretty good (there are a few warts on some
of the programs, and there are still reputed to be a fair number
of bugs in the library, though I've not encountered very many).
TDI is a pretty responsive company, and overall I recommend the
product.

I just copied a FONT LOADER accessory from CLUBII BBS. Problem is
that it doesn't do anything. Anyone have this? I have the fonts,
but no luck. They claim it uses DEGAS fonts. BUT, but, but...the fonts
they give as degas fonts load into degas all wrong. I checked them
with the DEGAS_FONT_EDITOR. And what I got is that in every little
rectangle that you are supposed to fit ONE letter, they crunched TWO
in. So, if I try using it with degas, everytime I press a key, two
letters get printed, one on top of each other. What to do? I checked
several other BBS across the nation, and all that carry DEGAS fonts,
have the fonts with the same problem. So, there must be something I
am doing wrong. Not everybody in the nation would have damaged fonts
up there. HELP!

Rick
(Flash%UMASS.BITNET)

Of course almost any CPU can replace any other if the proper hardware
glue is installed. The much larger problem is handling the kernel level
problems. As I'm sure your aware the stack frames generated by the 68020
(and 010) are not all together compatible. The kernel has to look at the
stored format number or it's a gone'r.

I have read benchmarks that indicate that the ST floppies are rather slow.
The most likely culprits are GEMDOS and the floppy driver code. I haven't seen
GEMDOS code (I certainly would like to!), but I have looked at the driver code.
It really isn't as optimized as it could be.

In fact it is far too understandable to have been optimized! :) :)

But seriously, while looking at the code I discovered something I would like
to pass on:

If the buffer that is specified in a read or write operation is not on a word
boundary, the resulting operation is going to be VVEERRYY SSLLOOWW!! The main
reason for this is that the DMA buffer must be on a word boundary. If the user
buffer is not on a word boundary, the driver must read a sector at a time into
its own word aligned buffer and copy it to the user buffer. If the buffer
IS word aligned, then it merely DMA's the requested sectors into the user buffer
straight from the floppy.

Needless to say, the second option is much faster.

Moral: In your programs, always try to use a word aligned buffer for disk
requests.

   On the July issue of Computer Current, I leaned there is a $300 module that plugs into the cartidge port of the ST allows it to run almost all the Macintosh software. Could someone out there in the netland give me more infor on this?
   Could someone also give me a brief review on the 1040 ST developer package?

Thanks,

Nelson

THE BAD
The quality of information in the Abacus books is suprisingly
poor. They contain an enourmous amount of misinformation and
stuff that's just plain /wrong/. I would stay away from these
books, like the plague. The consensus in Atari's software
engineering department is that they're not worth much.

THE GOOD
The Mark Williams C Compiler is shipping. It looks like a
real good job. The compiler is (comparatively) fast, its
documentation is good, and it comes with some nice tools
(make, and so on).

THE MISUNDERSTOOD
We've received several applications here that appear to
depend on the ST's operating system being located at
0xfa0000. This is a no-no. Use the system variable
`_sysbase' (long at 0x4f2) which points to the base of the
running system.

I respectfully suggest that the prices quoted above are
representative of the company buying the parts, and not what
the parts really cost.

> experiences with this format and does it hurt the drive in anyway?

It will *not* damage the drive. You may find the disk format
unreliable, however. The speed problem may be related to
interleave --- it depends on how the program does the format.

Typically these programs format a disk with 10 512-byte sectors
per track. This could cause problems if your drive's rotational
speed varies more than 1.7%.

Adding tracks is also a no-no. The drives are spec'd to 80
tracks; any tracks outside that range should not be considered
reliable.

The ST uses a DMA chip for very fast disk reading. Notice, for example, how
fast a long program loads (listen to the clicks as the tracks go by).
The problem with many programs that read/write files very slowly is that
they do it UNIX style, char by char. (It is buffered somewhat (sectorwise?)
but not enough.) The disk spins as the data is handled, and then is not on
the next sector when it's needed, meaning that everything waits till the disk
goes around almost a whole circle. With 9 sectors per track this causes aprox.
an 8-fold slow-down. This is NOT the way to do it! My new version of
microEMACS includes a method of reading (and writing) files through a big
(18K) RAM buffer (you've got a Megabyte: use it!). The speed improvment is
VERY noticeable. It is almost as fast reading a long text file into the
editor (from floppy) as it is copying the file to RAM disk.

In the future we will all have hard disks, it seems. Then it is even MORE
important to use a good buffering scheme. Personally, I believe that this
should be done at the operating system level, as some sort of disk caching.
The methods that worked for UNIX (with big, fast hard disks and a slow CPU

managing a small (per user) block of RAM) are NOT good for us micro users (with a great CPU (for one user) and slow hard disks (or worse)). Until things get better, I do most of my work off a RAM disk (compile and link a 100-line program: 15 seconds! (using Megamax)).

Well actually, the atari buletin board is five numbers:

(408) 745-5308
         -5970
         -2642
         -4758
         -5664

each of which connects you to a different line.

     You get a different login number for each line you manage to connect to, and although the download database is shared, the message databases are not.

     What makes it fun is that the lines are on a roter, so that you don't necessarily get the line you call. . .

"It's a desert topping!"

     "It's a floor wax!"

Stop! You're both right! 327x is the designation of a family of
IBM display products. They include very dumb terminals that are the
display stations Dave refers to, as well as the relatively intelligent
control boxes, shared between multiple display stations, that Rex speaks
of. The interface between the tubes and the controller is a 2 Mbit/sec
(if I recall correctly) synchronous serial line with a proprietary
encoding scheme. The interface between the controllers and their
hosts can be a serial interface running SNA/SDLC or BSC, or a direct
channel connection. I assume they will put them on their token ring
as well, sooner or later.

Emulating a 327x display station with an Atari or any other personal
computer currently on the market is out of the question without a
significant hardware assist. Emulating a "remote" control station
would just take a lot of rather tricky software work.

==========
Date: 25 July 1986, 10:19:53 GMT
From: Simon Poole   K538915 at CZHRZU1A
To: INFO-ATA at SU-SCORE

Subj: Wanted: terminal emulator with 132 columns

(I'm writing this in reply to a message I read on UUCP, so maybe this
 response will be at info-atari16 before the original letter)

Leo,
  I just finished writing a VT100 emulator with a Tek4010 vector mode with zooooooooom (probably I'll post it to the net some time) and one of the two things I haven't implemented (yet) is 132 columns, the other is double height/width characters. I just don't see how it can be done without scrolling sideways, to get 132 characters on one screen you need a 4x6 (or 4x8 or 4x16) font and I just don't belive that you will be able to read it at all (you can hardly read it on a VT100), if a scroll sideways (or rather jump sideways) mode would be enough I probaly could build that into my program.

               Simon.

P.S. Neil, its awfully frustrating reading about all the PD programs you have
     on the Atari BBS and having no possibility at getting them (hint, hint).

The order that auto programs get executed is simply the order that they are placed in the auto folder. I.e., the first program you copy into the auto folder will be the first one executed (until you delete that program, natch).

Disclaimer -- my humble opinions are not worthy of disclaimers. Besides, they're absolutely RIGHT!

Prospero Fortran has been available (from the U.K.) for, oh, a month or two.
Unfortunately, it was not reviewed too positively in the latest Antic. The
reviewer did some sort of benchmark, and probably did it wrong, because the
guy I know who has Prospero Fortran wrote the same benchmark and it executed
in about 1/20th of the time that the reviewer listed.
Prospero has ads in Antic, I think. Check it out there.

My 1040STf behaves the same way. I wonder too. Maybe we both have
a bad auto program. I don't remember the details, but my auto
folder contains a clock setting program (currently a freebee from
Batteries Included, previously some other freebee).

> (BTW - is there any way to control the order in which programs
>in the auto folder get executed?)

I suspect that the order the .prg files are found in the auto folder
control the order in which they are executed. This order is hard to

observe or control. Here is my recipe:
     - remove all files from the auto folder
     - add the .prg files back in the order you want them executed

Gosh Landon ---
   If the boys at Atari feel the Abacus information is often
inaccurate (which, no doubt, is true), then why don't you produce
some decent documentation yourselves at a reasonable price. (Sorry,
but I don't consider paying $300.00 for some books and a so-so C

compiler any great shakes. Very IBMish...naughty-naughty.)
   The Abacus books are flawed, but they at least give us a starting point to work from...plus they are only $20 each...

   One more complaint: I paid $900 for a machine that I really like, but it came with a comic book for documentation. 6 monthes after I have my machine, I find out (thru the net, so thank you to all those on the net) that it has all sorts of little interesting features like: hitting the right mouse button to grab something from an inactive window, hitting ALT-HELP at anytime to produce a screen dump, etc.

   What is Atari doing, punishing me for not paying an additional $300 for the "developer's" kit by withholding useful information about a machine I already paid for? Ick.

   Atari has on its hands an excellent product...but it's support leaves a lot to be desired...

Thank you for giving the information. Just out of curiousity, did you
fix the perverse usage of the high address bits so that a 68010 or 68020
could be used in place of the 68000?

You forgot to caution against jumping into the ROM for any reason. This
shouldn't be necessary for the ST since almost all of the "useful routines"
are available as "system calls" or exceptions. Let's hope we can avoid
the "hacker tactics" used on the Atari 800, Apple II, and IBM-PC. Otherwise
Atari can't come up with better versions and bug fixes.

Landon, maybe you could give some "ground rules" about "hostile applications"
that "take over" vectors for private use. Definately not reccomended if
Atari plans to go to multi-tasking in a future ROM release.

Lines: 18
Keywords: same as single-sided, ROM TOS

Double-sided disks are in the same logical format as single-sided disks:

the logical sector numbers all have the same interpretation. The difference
is physical: the sectors are laid out on alternating sides. Logical sectors
0 to 8 are Track 0, Head 0, Sector 1 through Sector 9. Then you go to the
Head 1 for logical 9 to 17, and back to Head 0 on the next track for 18 to
24. Since the disk is bigger, the FAT is usually larger, or the cluster
size larger, or both, so you should be careful to interpret the information
in the boot sector correctly (sectors per fat, sectors per cluster, etc).

About Fonts: There was a font-loader accessory from a magazine (Antic?)
which actually overwrote the font information in RAM. This worked only
under RAM TOS (obviously). I am not familiar with font loaders for ROM
TOS, except that they exist. Perhaps somebody else on the net can speak up?

A company called Prospero software has an ST implementation called
Pro Fortran. There is (I think) another Fortran by Absoft, the people
who wrote Microsoft Fortran for the Mac. You might look in ANTIC magazine
for ads.

I don't know anything about either of these, as my interest in Fortran
is less than epsilon.

>--
>   Tom Erbe

I found just the opposite. If you are comparing to the speed of the Mac
drives, which are "Incredible Woz Machine" technology, then yes, the ST
is a little slower.

SONY actually make 3 1/2" drives in several flavors, each with different
rotational speeds and Seek times. Atari went with a shorter seek time,
but standard rotational speed, appearantly to allow the use of 5 1/4"
inch drives (Which can be interfaced by simply buying a "replacement cable"
and a little soldering/connecting).

The main question is, can the existing drive be put into 2X or 4X rotational
speed? Can the clock on the WD chip be multiplied as well?

If you really want speed, get a Kodak "second drive" and a Supra SCSI
adapter. Then you can get 3MB/disk using special "high density disk",
that give you hard disk (1800 or 3600? RPM) speeds.

The thing to remember is that the "floppy" (either size) should normally
be used as a "download and bootstrap" device once low-cost high-speed
storage is available. Considering that a hard drive could be built

from "surplus" for around $350, maybe less, it makes sense to go with
something "hard".

I would be interested in comments on the Atari ST Developers

Package. I have a 1040. Is the documentation applicable to the
1040 as well as the 520? Are there other sources of system
details? I have "Presenting the Atari ST" and Compute!'s "ST
Programmer's Guide" but they are of little use for C programming.

Thanks
-Dennis

I'm interested in getting information about hard disks available
for the ST.
If anyone has the technical information about existing ST hard disks
please E-mail me and I'll summarize to the net.
Also, is it possible to connect hard disks from other micros to the
ST?
An IBM-PC hard disk for example?

Guy

Summary: Get your supra board now!!!

This, among others, was found in net.micro.mac, however, I thought
it might be of interest to ST users as well, I would simply suggest
looking through net.micro.mac to see more options on an SCSI drive.

In article <106@van-bc.UUCP> sl@van-bc.UUCP (Stuart Lynne @ SLI) writes:
>In article <541@hope.UUCP> deano@hope.UUCP writes:
>>   The Challenge of the week....

>>the MAC+ SCSI Port. The Way I understand it is...

With the ST, you will need to get an SCSI adapter, I currently know
about the Supra card, let's hope others follow, especially Atari.

(Neil, any chance of a $100 SCSI interface?).

>>1. Get an off the shelf hard drive at your local electronics surplus.
>>2. Hook a SCSI Disk controller to the drive.
>>3. Hook the controller to the MAC+ SCSI port (custom cable?)
>>4. Tell the Mac that there is a H.D. (modify H.D. 20 DOC.?)
>>5. format dialog should magically appear, and your on your way.

>There are other SCSI compatible drives about to come onto the market. Priam
>with a 60MB, Quantum 80MB, Maxtor 240MB, CDC 240MB, etc. For the most part
>embedded SCSI will simplify your life when you write the driver (for example
>no need to tell the controller about the disk geometry, its in it's firmware
>so just say format and away you go). Also embedded SCSI is allowing the
>manufacturers to lower their prices by improving their production yields.
>(Because they handle the format, they can use advanced slip sector techniques
>to eliminate bad sectors, allowing them to use what would have been a bad
>platter if it had been put into a 506 style drive.) It also allows them to
>use RLL encoding or other techniques to increase the storage without adding
>extra heads/platters. Priam uses this technique to make a 60MB SCSI out of
>a 40MB ST506 drive.

This "absolute purity required" has resulted in a number of "surplus"
ST-506 drives available as "used" that could still work effectively with
a good SCSI controller. It may be possible to get a $100 controller,
and a $100 drive, and have a hard disk for as little as $400, including
Supra card.

>So we should see an avalanche of large, cheap SCSI drives in the final
>quarter 1986.

Especially considering there is also an SCSI card for the "PC" now. If
Atari either upgrades their DMA port, or comes out with their own SCSI
adapter, the drive options would be unlimited.

I haven't heard from Atari on this one, at least the Supra card is available.
Kinda makes an "integrated drive" from Atari look dissappointing doesn't it?

[]

The compiler bugs (especially in the floating-point package) keep
wasting my time... - here are some tidbits that might save YOU some time:

The Megamax library does not have a fabs() function, and abs()
does not always work right for FP. So I added this to math.h:

```
#define fabs(x) (((x)<0.0)?(-(x)):(x))
```

The transcendental functions do NOT warn you if the argument passed to
them is illegal. You get GARBAGE (and you don't even know it!), or it
crashes, or (in the case of log(0)) it HANGS!

I now use LOG() and SQRT() instead of log() and sqrt(). The following
functions were also added to math.h:

```
double LOG(x)
     double x;
{
     if (x <= 0.0) {
          fprintf(stderr,"illegal arg for log()!\n");
          exit(0);
     }
```

```
        x = log(x);
        return (x);
    }

    double SQRT(x)
        double x;
    {
        if (x < 0.0) {
            fprintf(stderr,"illegal arg for sqrt()!\n");
            exit(0);
        }
        x = sqrt(x);
        return (x);
    }
```

If your program gets into an infinite loop, or just a loop that's too long, there is no way to stop it unless it's doing I/O. To enable that, add the statement "keybrk();" here and there in your loops, and #include the following file at the top of your source:

```
    /* Check if a key has been pressed, and if it was
     * a control-C print message and exit
     */

    #include <osbind.h>

    keybrk()
    {
        if (Cconis()) {                  /* any key pressed? */
            if ((Crawcin()&0x7F) == 0x03) {  /* is it ctrl-C?    */
                fputs("\nbreak!\n\n", stderr);
                exit(0);
            }
        }
    }
```

Finally, the simple random-number generator, defined as a macro in stdio.h:

```
    extern long _seed;
    #define srand(x) _seed = x;
    #define rand() (int)(_seed * 6907 + 130253)
```

is no good because a call to rand() does not update _seed, so you keep getting the same nonrandom number again and again! Change to:

```
    #define rand() (int)(_seed = (_seed * 6907 + 130253))
```

Don't forget to do an srand(SEED), with SEED some integer, or else you'll get the same sequence each time you run the program. For an unpredictable sequence (good in games, for example) use the current (encoded!) time as SEED!

If you want a floating-point version, returning a number between 0 & 1:

```
    #define RND  ((double)(rand())/65536.0 + 0.5)
```

(But I would NOT recommend this kind of random number generator for
 serious statistical purposes!)

```

I've just written a demonstration program mostly as an exploration of my ST. It's a multiwindow file browser, which allows you to look at up to ten files in GEM windows. You can open and close files, and move forward or backward through the files you are looking at.

My next four messages will consist of a description of the program, the source code for the program, and the source code for each of two support routines.

The main program I wrote, and place fully in the public domain. The only restriction I place is that you credit me if you use the code. The support code I got from OSS's buletin board.

Yes, I know this is buggy, and there has to be a faster way to handle window updates and scrolling, and no I'm not going to support it, but I would be interested in any positive criticism.

This file contains the readme for my OSS Pascal demo

----- CUT HERE -----

pager.pas is a simple application in OSS Personal Pascal for the Atari ST. I wrote it on a monochrome 1040, but it should work on any system at any resolution.

My intent was to experiment with the GEM interface from Pascal, and try to write some kind of "template" program I could use as a basis for more sophisticated programs later.

Pager is a multiple window file viewer. Files may be opened or closed, and viewing can scroll forward or backward. Pager is organized around the simplest possible event driven loop:

```
Initialize
While still running
get an event
deal with it
Clean up
```

Pager will handle all of the events returned by Get_Event, although it ignores the right mouse button, only performs limited menu service, and only pays attention to the first cursor rectangle event.

Pager also uses built in dialogs, as well as alert boxes, and responds to menu entries. It also demonstrates XBIOS calls as well as timer events.

It does not build it's own dialogs, and doesn't use mouse position information.

Pager starts by offering the user an alert box which allows him to immediately abort the program. If he chooses to continue, pager opens the first file, using the built in "Item Selector" dialog.

In order to spread the overhead of reading files around, the entire file is not read in immediatly, but rather only enough to fill the default window, which is full screen size.

Pager than enters it's procesing loop, which consists mostly of waiting for events to occur and then responding to them.

An unusual event that pager responds to is a ten second interval. If no activity has happened within the last ten seconds, pager will put an alert box up indicating how long it has been since pager has started.

This alert is simply a demonstration of the interval timer, as well as using XBIOS calls to access supervisor memory.

The events which pager responds to are message events, keyboard events, timer events, 'rectangle' events, and button pushed events.

Since pager is a template, I made up a silly use for the rectangle and button events. The cursor takes one of four shapes, depending on the mouse being in or out of the front window, and the left mouse button being down or up. In pager, these cursor shapes don't have any real meaning, they are just window dressing.

Most keyboard events (key strokes) are ignored. However, the HELP key causes a HELP alert box to be posted, which would contain something a litte more useful in a serious program, and the UNDO key causes the quit alert box to be posted.

Most of the work occurs in message events, which fall into several catagories. There are selection events, redraw events, top events, close events, fulled events, arrowed events, horizontal events, veritical events, size events, and move events.

A selection event occurs when the mouse is clicked on a menu selection. Pager allows desk accessories to work and has four menu entries of its own. A menu event can be used to open a new file, to close an open file (and it's window,) to quit the program, or to get an "about pager" alert box.

A close event occurs when the close box has been clicked, and causes pager to close the file, close the window, and free up any related storage.

A full event occurs when the full box has been clicked. Pager uses the full box as a toggle event. If the window is already full, than it is resized to be the last size it was set to by other than a full. If it's not full, then it's set to cover the entire screen.

Since windows start out as full screen size, pager starts with the assumption that the first 'small' size for a window should be 1/4 the screen size, located in the upper left hand quarter of the window.

Size events simply cause the window to grow or shrink, in response to clicking the size box and dragging. Pager allows the window to assume any size.

Move events simply cause the window to be displaced, in response to clicking the title bar and dragging. Pager will allow the window to be placed anywhere GEM will put it.

Arrow events occur from clicking in the elevator bar, or on the arrows at the ends of the elevator bar. Pager responds to arrow clicks by moving the page up or down one line, or by moving the display left or right one character. Pager responds to elevator bar clicks by moving the page up, down, left or right one window full, as appropriate.

Because files are only read as needed, the code for keeping track of the position in the file is a fairly crude, although it appears to be bug free.

However, the code for calculating the position and size of the elevator cars is slightly buggy, suffering from some calculation round off errors which cause the cars to sometimes do nonintuitive things.

Also, until the file has been entirely input, it is not possible to know the full size of the file, so a heuristic is used for the vertical elevator. One full window size is added to the currently known size of the file when calculating the postion and offset of the elevator, so there will always be room to click on either side of the bar until the entire file has been read. Once the entire file is read, the actual file size is used.

Horizontal and Vertical events occur when the elevator car has been clicked and drug to a new location. In this event, Pager calculates the correct viewing offset according to the new positions of the elevator cars and redisplays accordingly.

There is room for much improvement in this area, since "scrolling" consists of erasing and redrawing the entire window, rather than moving the still visible part and adding new data.

The most interesting event Pager has to deal with is the Redraw event, which occurs when a portion of a window which was previously invisible becomes visible.

As you are probably aware, GEM keeps lists of 'visible' rectangles which make up each of the windows. The most efficent way to update a window would be to only redraw the portions which weren't visible before, but which are now.

Unfortunately, what Pager does is to go through the list of visible rectangles, setting the clipping region to the part just made visible and redrawing the entire window. This is the second area where there is much room for improvement.

Pager tries to be relitively bug free and robust, and seems to succede moderately well, (except for the elevator calculations mentioned before.) However, one are where I systematically did an unsafe bit of coding was in obtaining memory. None of the places where new is called to obtain more memory, is there a check for failure. This will probably lead to unpleasentness eventually, and I will probably fix it one of these days.

In writing pager, I discovered that the built in read procedure will not read character data from other than a text type. Since I was considering using random file access to facilitate memory management, I wrote a "Get_string" routine, which will allow me to expand to random access if I need it.

Overall, I have been very impressed with Personal Pascal. I have managed to fairly sophisticated programming using only it, it's manual, and the ABACUS "Internals" manual. It is reasonably bug free; I only found two problems with it while writing pager. It is reasonably easy to learn; I've only had it for two weeks, and pager is only about six hours work. (Although I have had a lot of pascal experience before.) It runs reasonably quickly; pager only takes about fifty seconds to compile and link using a ram disk on my 1040ST. The support from OSS is good. and the price is right.

I've also been very impressed with the 1040ST. I've got a MacUgly (used to have a girl's name) sitting on my desk at work, complete with full blown Aztec C, and I still haven't managed to get anything as complete at pager working using it's interface. (I also have a lot of C experience, since hacking Unix kernels is my living.)

All in all, I'm glad I've got the beasty.

Marty

This is the last part of my OSS Pascal demo.  It is the file
strval.pas.  I did not write it, but got it from the OSS PASCAL
buletin board.

     Place strval.pas, peekpoke.pas, and pager.pas in the same folder and
compile pager.pas, using the GEM option on the compiler.

----- CUT HERE -----

{***
 *   Floating Point Conversion routines.
 *   From Real to String and String to Real
 *
 *   By Kevin L. McGrath
 ***}

PROCEDURE Str(Value: Real; VAR St: String);

{* Notes:
 *   This routine is only accurate up to 9 digits becuase of the LongTrunc.
 *   It HAD rounding errors, but they are now fixed (with the LongTrunc)
 *
 * O.S.S. Pascals Floating Point Format:
 *   This is just a guess, but here goes...
 *   One byte of exponent biased by 128 to give a +38 to -38 range.
```

```
 *   Fourty bits of mantissa to give 11 digits of accuracy, One bit sign.
 *   Most floating points are normalized to the left, with the point between
 *   the most significant bit of the mantissa and the second most, so I think
 *   this is two.  To find out, just plug out a routine that has a pointer
 *   to a real, coerce's it into a pointer to a record structure of byte like
 *   this:
 *     Record
 *       Exponent:      Byte;
 *       MantissaOne:   Long;
 *       MantissaTwo:   Long;
 *       MantissaThree: Long;
 *     End;
 *   then you can extract the exponent and mantissa just by doing a
 *   "Ptr.Exponent" or somethin like that.  Well, I haven't had time to get
 *   that fancy with this, but I have used this routine and am sure it works.
 *   Hope you guys at O.S.S. can vert it to some kind of normal ASM function!
 *      Good Luck...   (Nice Compiler)
 *      Call me if there are any probs, dig?

This is pager.pas, it's the third part of my OSS Pascal demo. Place this,
    strval.pas, and peekpoke.pas in the same file, and compile pager.pas.

- ----- CUT HERE -----
{
  pager.pas is a demonstration of the GEM interface, as exercised
  by OSS Personal Pascal.  Pager.pas is in the public domain, and
  may be used for any purpose, so long as the author is acknowledged.

This is really to James Turner, but I don't happen to have his
exact address handy... Sorry.

Well, I heard you're working on Unix & ST ports of the ARC program,
and I was wondering how it's been coming along. I've been trying to
do the same thing myself to a unix 4.2bsd system. I've got XARC
to almost completely compile, but there are 3 routines that the
source looks for that I really haven't figured out yet...
(I've got descriptions for 2 of them... I'll try to write my own
work around, eventually...) These are makefnam, filedir, and
setstamp. What have you been doing with these?

hi.

Gentlemen. We are in need of a quality schematic diagram
package for the 1040 ST. We have seen 'Graphic Artist' already
and found it lacking. We need something along the 'Futurenet'
or 'Scema' style package and component libraries. (IBM? Don't make me barf!)

Has anyone heard of anything currently avaliable?

Has anyone heard of anything on the way?

Let us know. Thanx.

Seems INTERNET is down, I oddles of bounceb-backs from there.

Anyway, first of all, does anybody still read this list? I get more
ST help from Info-Pascal and Info-68k than I do from here? Anybody
awake out there? So far I have asked a couple questions, and no serious
replies. Tsk tsk tsk.

Well, I have another one. I just learned a rumor than the SUPRA hard
drive is supposed to be MUCH faster than the Atari Hard drive. I am
planning to buy a hard drive, now if it is true that the SUPRA is faster,
I would not mind paying a couple extra dollars for a faster drive.
Any help out there, please????

BTW, any help on my previous questions on OSS Personal Pascal or
FONTLOADER?????

Rick

So what would you like me to do about it? That's why we have the BBS -- to
distribute the software. What alternatives are there? We'd like to go with
a national service (i.e. CompuServe, GENIE) but most of the software is there
already so obvoiusly you can't afford that. And we don't want to get into
the business of duplicating disks of the stuff (and having to support it).

Which is why we've been working on a reference book for commercial
publication. Hope to get it out by Xmas.
